## Head, Neck and Brain - Volume III

FOURTH EDITION

**Vishram Singh** MBBS, MS (LKO ), PhD (hc ), MICPS, FASI, FIMSA

*Adjunct Professor, Department of Anatomy, KMC, Mangalore, Manipal Academy of Higher Education (MAHE) Manipal, Karnataka, India*

*Editor-in-chief, Journal of the Anatomical Society of India*

*Chairman Expert Group, Research-in-Anatomy, Indian Council of Medical Research (ICMR), New Delhi*

*Member, Federative International Committee on Scientific Publications (FICSP) of IFAA, Geneva*

*Member, COPE Council (England and Wales)*

*Former Professor and Head, Department of Anatomy, Santosh Medical College, Member, Academic Council and Core Committee, PhD Course, Santosh Deemed to be University, Ghaziabad, NCR, Delhi*

*Project Editor, BI Churchill Livingstone, New Delhi*

*Examiner in National and International Universities; Member, Editorial Board, Indian Journal of Otology; Journal of Anatomy and Cell Biology; and National Journal of Clinical Anatomy , Ex-Vice President, Anatomical Society of India*

*Medicolegal Advisor, ICPS, India*

*Consulting Editor, ABI, North Carolina, USA*

*Associate Editor, Acta Medica International , Member British Association of Clinical Anatomists (BACA)*

*Formerly at: King George's Medical College, Lucknow*

*GSVM Medical College, Kanpur*

*Al-Arab Medical University, Benghazi (Libya)*

*All India Institute of Medical Sciences, New Delhi*

## **SECTION I. Head and Neck**

[1. Introduction and overview of living anatomy of the head and neck](#)

[Head](#)

Living anatomy of head

Regions of the head

Examination of oral cavity

Neck

Topographical organization of the neck

Living anatomy of neck

## 2. Osteology of the head and neck

Bones of head AN 26.1

Study of skull as a whole AN 26.2

Structures passing through various foramina, canals, and fissures on the outer aspect of skull AN 26.3

Differences between male and female skulls

Craniometry

Newborn skull

Study of individual skull bones AN 26.4

Cranial cavity AN 26.3

Bones of the neck

Hyoid bone

Cervical vertebrae AN 26.5

## 3. Scalp, temple and face

Scalp AN 27.1

Temple

Face

Muscles of facial expression/superficial muscles of face AN 28.6

Eyelids

Lacrimal apparatus AN 31.4

#### 4. Skin, superficial fascia and deep fascia of the neck

Skin

Superficial fascia

Deep cervical fascia (fascia colli) AN 35.1

Layers of deep cervical fascia

Fascial spaces (or tissue spaces) of neck AN 35.10

#### 5. Side of the neck, sternocleidomastoid muscle and posterior triangle

Sternocleidomastoid muscle (Fig. 5.3) AN 29.1

Posterior triangle AN 29.1

#### 6. Anterior region of the neck: Anterior triangle, ansa cervicalis and infrahyoid/strap muscles

Structures in the anterior midline of the neck

Anterior triangle of the neck AN 32.1

Infrahyoid muscles of the neck (strap muscles of the neck)

#### 7. Back of the neck, suboccipital region, cervical spinal column and joints of

neck

Back of the neck

Skin

Superficial fascia

Deep fascia

Muscles

Suboccipital region

Cervical spinal column and joints of the neck

Cervical vertebrae

Joints of the neck

Summary of atlanto-axial joints

## 8. Parotid region: Parotid gland and extracranial course of facial nerve

Parotid gland AN 28.9

Facial nerve: Extracranial course AN 28.4

## 9. Submandibular region

Muscles of the submandibular region

Nerves of the submandibular region

Blood vessels of the submandibular region

Salivary glands in the submandibular region AN 34.1

Submandibular ganglion (Langley's ganglion) AN 34.1

## Surgical muscular planes of the submandibular region

### 10. Temporal fossa, infratemporal fossa, temporomandibular joint and pterygopalatine fossa

Temporal fossa (Fig. 10.1)

Infratemporal fossa AN 33.1

Muscles of infratemporal fossa AN 33.2

Blood vessels of infratemporal fossa

Neural structures in infratemporal fossa

Temporomandibular joint AN 33.3

Fibrous capsule

Ligaments

Relations

Nerve supply

Blood supply

Lymphatic drainage

Stability

Movements of the mandible

Muscles of mastication AN 33.2

Pterygopalatine fossa

Boundaries (Fig. 10.23)

Communications

## Contents

### Third part of the maxillary artery

#### 11. Thyroid and parathyroid glands, trachea and oesophagus

Thyroid gland (Greek, thyreos = shield; eidos = form) AN 35.2

Parathyroid glands

Trachea

Oesophagus

#### 12. Pre- and paravertebral regions and root of the neck

Prevertebral (anterior vertebral) muscles

Paravertebral (lateral vertebral) muscles

Cervical plexus

Phrenic nerve (Fig 12.12)

Cervical sympathetic trunk/chain (Fig. 12.13) AN 35.6

Root of the neck

#### 13. Oral cavity, teeth and tongue

Oral cavity

Vestibule of the mouth

Teeth

Oral cavity proper

Tongue AN 39.1

## 14. Pharynx and palate

### Pharynx

Pharyngeal wall (Fig. 14.7)

Muscles of the pharynx

Deglutition (swallowing)

Palatine tonsils AN 36.1

Pharyngotympanic tube (SYN. Eustachian tube/auditory tube)

### Palate

Hard palate

Soft palate AN 36.1

## 15. Larynx

Skeleton (Fig. 15.3) AN 38.1

Joints

Ligaments and membranes

Muscles

Cavity of larynx

Phonation

## 16. Blood supply and lymphatic drainage of the head and neck

Blood supply of head and neck

Arterial supply

Veins

Carotid sheath

Styloid apparatus

Lymphatic drainage of the head and neck AN 28.5

Lymph nodes AN 28.5

## 17. Nose and paranasal air sinuses

Nose

External nose

Internal nose/nasal cavity

Lateral wall of nose AN 37.1

Paranasal air sinuses AN 37.2

Frontal air sinuses

Maxillary air sinus (antrum of highmore)

Ethmoidal air sinuses

Sphenoidal air sinuses

## 18. Ear: External ear, middle ear, pharyngotympanic tube and internal ear

External ear AN 40.1

Middle ear AN 40.2

Pharyngotympanic tube (Fig. 18.12) AN 40.2

Internal ear AN 40.3

## 19. Orbit and eyeball

### Orbit

Relations

Contents

Extraocular muscles of orbit AN 31.1

Fascia bulbi or fascial sheath of the eyeball

Nerves of the orbit AN 31.2

Ciliary ganglion (Fig. 19.15)

Ophthalmic artery

Ophthalmic veins

Lacrimal gland

Orbital fat

Eyeball (bulbus oculi) AN 41.1

Tunics/layers of the eyeball AN 41.1

Arterial supply of the eyeball

Compartments of the eyeball

Lens

Functions of the eye

Refractive media of the eye

## 20. Vertebral canal and spinal cord

### Vertebral canal

Contents of the vertebral canal AN 42.1

Spinal meninges

Spinal cord

External features (Fig. 20.6) AN 57.1

Internal structure AN 57.3

Tracts of the spinal cord AN 57.4

Blood supply of spinal cord

## 21. Cranial cavity, cranial meninges and pituitary gland

Cranial cavity

Skull cap (calvaria)

Subdivisions of the cranial cavity AN 30.1

Cranial cavity and meninges AN 30.3, AN 56.1

Cranial dura mater

Intracranial dural venous sinuses

Other dural venous sinuses

Pituitary gland

## 22. Cranial nerves

Olfactory nerve

Optic nerve

Oculomotor nerve

Trochlear nerve AN 31.5

Abducent nerve AN 31.5

Strabismus/squint

Trigeminal nerve AN 31.5

Facial nerve

Vestibulocochlear nerve

Last four cranial nerves AN 35.7

Glossopharyngeal nerve

Vagus nerve

Accessory nerve

Hypoglossal nerve

## **SECTION II. Brain**

### **23. Overview of brain, meninges and cerebrospinal fluid**

Brain

Base of the brain

Ventricles of the brain

Membranes of the brain (meninges) AN 56.1

Subarachnoid space

Cerebrospinal fluid (CSF) AN 56.2

### **24. Brainstem and functional column of cranial nerve nuclei**

Medulla oblongata

Pons

Midbrain

Development of functional columns and nuclei in brainstem

Reticular formation

## 25. Cerebellum and fourth ventricle

Cerebellum

External features AN 60.1

Subdivisions of the cerebellum

Internal structure AN 60.1

Connections of cerebellar cortex AN 60.2

Arterial supply of the cerebellum

Fourth ventricle AN 63.1

Boundaries

## 26. Diencephalon and third ventricle

Diencephalon

Divisions and subdivisions

Hypothalamus AN 62.5

Third ventricle AN 63.1

Boundaries AN 63.1

Recesses

Choroid plexus and tela choroidea

## 27. Cerebrum

External features of the cerebral hemisphere AN 62.2

Lobes of cerebral hemisphere

Cerebral cortex

White matter of cerebrum AN 62.3

Lateral ventricles AN 63.1

Parts of lateral ventricle (Fig. 27.6)

Choroid plexus and choroid fissure

## 28. Basal nuclei and limbic system

Basal nuclei AN 62.4

Parts

Functions of basal nuclei

Limbic system AN 62.4

Functions of limbic system

Components of limbic system

Amygdaloid nuclear complex

Hippocampal formation

Fornix

Mammillothalamic tract

## 29. Blood supply of the brain

Arteries of the brain

Arterial supply of cerebrum

Venous drainage of the brain

Cerebral veins

## 30. Surface anatomy of head, neck and brain

Head and neck

Parotid gland AN 43.6

Parotid duct

Facial artery in the face AN 43.6

Pterion AN 43.6

Facial nerve AN 43.6

Submandibular gland AN 43.6

Mandibular and inferior alveolar nerves

Lingual nerve

Thyroid gland AN 43.6

Isthmus

Lateral lobes

Brachial plexus

Spinal accessory nerve

Subclavian artery

Common carotid artery AN 43.6

External carotid artery AN 43.6

Internal carotid artery AN 43.6

External jugular vein AN 43.6

Internal jugular vein AN 43.6

Subclavian vein AN 43.6

## Brain

Superolateral surface of cerebrum

Central and lateral cerebral sulci

Functional areas of cerebral cortex

Multiple choice questions

### *My Parents*

**Late Smt Ganga Devi Singh and Late Shri HR Singh,**  
an ever-guiding force in my life for achieving knowledge through education  
and clinical practice

### *My Wife*

**Late Mrs Manorama Rani Singh**  
for tolerating my preoccupation happily during the preparation of this book

### *My Elder Brother*

**Shri Kaptan Singh**  
for his sacrifices to me

### *My Teachers*

**Late Professor (Dr) AC Das**  
for inspiring me to be multifaceted and innovative in life  
**Professor (Dr) A Halim**  
for imparting in me the art of drawing good line diagrams and good teaching

### *My Students, Past and Present*

for appreciating my approach to teaching anatomy and transmitting the  
knowledge through this book

---

# Preface to the fourth edition

---

It is a matter of great pride to present fourth successive edition of *Textbook of Anatomy: Head, Neck and Brain, Volume III*. This book is widely used not only in India but abroad also by the undergraduate and postgraduate students of anatomy. The popularity of this book reflects the appeal of its concept-building approach and easy-to-understand language with neatly redrawn line arts. This approach has been retained in this edition as well. Based on a large number of suggestions, criticisms and feedback received from the students and fellow academicians, following major changes have been done.

- The competency codes are integrated within the text in accordance with the competency-based curriculum of anatomy as per the revised guidelines of National Medical Commission (NMC).
- Most of the diagrams are completely revised and redrawn by the author himself for easy understanding and reproducibility in the exam.
- The chapters on [Chapter 4](#) Skin, superficial fascia and deep fascia of the neck, [Chapter 5](#) Side of neck, sternocleidomastoid muscle and posterior triangle, [Chapter 6](#) Anterior region of the neck: anterior triangle, ansa cervicalis and infrahyoid/strap muscles, [Chapter 7](#) Back of the neck, suboccipital region, cervical spinal column and joints of neck, [Chapter 11](#) Thyroid and parathyroid glands, trachea and oesophagus, [Chapter 17](#) Nose and paranasal air sinuses, and [Chapter 24](#) Brainstem and functional column of cranial nerve nuclei are thoroughly revised and updated. Based on a large number of suggestions from students and fellow academicians, a new chapter on Surface anatomy of head, neck and brain has been added at the end of book to appreciate the significance of living anatomy.
  - Many new line diagrams and halftone figures have been added and earlier diagrams have been updated. Also in this edition, Specific learning objectives including relevant applicable competency codes have been given at the beginning of each chapter to

emphasise the importance of topics to be learnt more carefully. In view of present trend of using imaging modalities by clinicians, a large number of new radiographs including plain radiographs, ultrasonographs, CT scans and MRI have been provided.

- Clinical correlations providing anatomical basis of common clinical conditions have been presented in boxes, to provide clinical orientation to students, which will help them immensely during their clinical years.

I highly appreciate the constructive suggestions that I received from past and present students, colleagues and faculty members from various corners of the country for improvement of the content of this book. I do not claim absolute originality of the text and figures other than the new mode of simplification, presentation and expression.

Once again, I wholeheartedly thank students, teachers and fellow anatomists for inspiring me to publish this edition. I sincerely hope that they will find this edition more interesting and useful than the previous ones. I welcome comments and suggestions from students and teachers for further improvement of this book.

*“Anatomy provides basis of clinical practice.”*

**Vishram Singh**

---

# Preface to the first edition

---

This textbook on head, neck and brain has been carefully planned for the 1st year MBBS students. It follows the revised anatomy curriculum of the Medical Council of India. Following the current trends of clinically oriented study of anatomy, I have adopted a parallel approach—that for imparting basic anatomical knowledge to students and simultaneously providing them its applied aspects.

To help students score high in examinations, the text is written in simple language. It is arranged in easily understandable small sections. While anatomical details of little clinical relevance, phylogenetic discussions and comparative analogies have been omitted; all clinically important topics are described in detail. Brief accounts of histological features and developmental aspects have been given only where they aid in understanding of gross form and function of organs and appearance of common congenital anomalies. The tables and flowcharts summarise important and complex information into digestible knowledge capsules. Multiple-choice questions have been given chapterwise at the end of the book to test the level of understanding and memory recall of the students. The numerous simple four-colour illustrations further assist in fast comprehension and retention of complicated information. All the illustrations are drawn by the author himself to ensure accuracy.

Throughout the preparation of this book, one thing I have kept in mind is that anatomical knowledge is required by clinicians and surgeons for physical examination, diagnostic tests and surgical procedures. Therefore, topographical anatomy relevant to diagnostic and surgical procedures is clinically correlated throughout the text. Further, clinical case study is provided at the end of each chapter for problem-based learning (PBL) so that the students could use their anatomical knowledge in clinical situations. Moreover, the information is arranged regionally because while assessing lesions and performing surgical procedures, the clinicians encounter region-based anatomical features. Due to propensity of fractures, dislocations and peripheral nerve lesions in the upper limb, there is in-depth discussion on

joints and peripheral nerves.

As a teacher, I have tried my best to make the book easy to understand and interesting to read. For further improvement of this book, I would greatly welcome comments and suggestions from the readers.

**Vishram Singh**  
New Delhi, 2009

---

# Acknowledgements

---

At the outset, I would like to express my gratitude to Prof (Dr) A Halim, my teacher and former Prof and Head, Department of Anatomy, King George's Medical University, Lucknow, for creating my interest in anatomy. I learned not only the art of good teaching but also the art of drawing good, simple and technically accurate line diagrams from him. May God bless him with long life.

I sincerely thank my colleagues in the Department, especially Prof Rajanigandha Vadgaonkar (HOD), Prof Mangala M Pai, Prof Latha V Prabhu, Dr B V Murlimanju and others for their cooperation and appreciation of my work.

I highly appreciate the help provided in reviewing the proofs of the whole text, by Dr C S Ramesh Babu, Former Professor and HOD of Anatomy, Lala Lajpat Rai Memorial Medical College, Meerut, UP.

I gratefully acknowledge the feedback and support of all my fellow colleagues in Anatomy throughout India, particularly:

- Profs Punita Manik (HOD), Anita Rani, Jyoti Chopra, Archana Rani, Rakesh Kumar Dewan, Garima Sehgal, R K Verma and others King George Medical University, Lucknow, UP.
- Prof A Shariff (HOD), AIIMS, New Delhi.
- Prof Vandana Sharma (HOD), Gandhi Medical College, Bhopal, MP.
- Profs S K Jain (HOD) Nidhi Sharma and others, Teerthanker Mahaveer Medical College, Moradabad, UP.
- Prof Ruchira Sethi (HOD), Uma Nath Singh Medical College, Jaunpur, UP.
- Profs Yogesh Yadav (HOD) and Pratishtha Potdar, NIIMS, Greater Noida, UP.
- Prof L Peter Ericson (HOD) and Dr D Krishna Chaitanya Reddy, Assistant Professor, KAMSRC, Hyderabad.
- Prof Bipin Khade (HOD) Chirayu Medical College, Bhopal, MP.
- Prof T S Roy (HOD) and Dr Preeti Shrivastava (Associate Professor),

NDMC Medical College and Hindu Rao Hospital, Delhi.

- Prof N C Goel, Vice Principal and Dr Shweta Singh, Acting HOD, Hind Institute of Medical Sciences, Barabanki, Lucknow, UP.
- Prof (Emeritus) P K Sharma, Era Medical College, Lucknow, UP.
- Prof Poonam Kharb (HOD), ITS Dental College, Ghaziabad, UP.
- Prof T C Singel, Dr M K Shah Medical College, Gandhinagar, Ahmedabad, Gujarat.
- Profs Vandana Mehta (HOD) and Hitendra Lohiya, Vardhman Mahavir Medical College, New Delhi.
- Prof Sneh Agrawal (HOD), Lady Harding Medical College, New Delhi.
- Prof Shashi Raheja (HOD), Dr Baba Sahib Ambedkar Medical College, Rohini, New Delhi.
- Prof Vanita Gupta (HOD), GS Medical College, Hapur, UP.
- Profs S L Jethani (Medical Superintendent) and Deepa Singh (HOD) and Akshya Dubey, Himalayan Institute of Medical Sciences, Jolly Grant, Dehradun, Uttarakhand.
- Prof W M S Johnson (Dean) and Dr Jaya Kumari, Sree Balaji Medical College, Chennai.
- Prof Suniti Pandey (HOD), GSVM Medical College, Kanpur, UP.
- Prof G M Mahesh, Basaveshwara Medical College, Chitradurga, Karnataka.
- Prof Deepti Shastri (Dean), VMKVMC and Hospital, Salem, Tamil Nadu.
- Profs L C Prasanna (HOD), Sneha Guruprasad Kalthur and Dr Prakash Babu, KMC, Manipal, MAHE, Karnataka.
- Dr S D Joshi, Director Professor of Anatomy, Sri Aurobindo Medical College.

I would also like to express my deep sense of regards to renowned anatomists of India, especially to Prof A C Das, my teacher (Anatomist, Surgeon and Radiologist), Prof Inderbir Singh, Prof Mahdi Hasan, Prof Indra Bhargava, Prof Shamer Singh, Prof A K Datta and Dr B D Chaurasia, who had inspired me a lot during my student life and teaching carrier.

Lastly, I thank my daughter, Dr Rashmi Singh; son Dr Gaurav Singh and daughter-in-law Ms Anupama Singh for helping me in the preparation of this manuscript.

I gratefully acknowledge the help and cooperation received from the staff of

RELX India Pvt Ltd, especially Arvind Koul (Sr Content Strategist), Shabina Nasim (Head, Content Project Management) and Anand K Jha (Content Project Manager) in completing the project on time.

# Reviewers

---

I would like to give special thanks to those who have reviewed the digital copies of this book, before publication.

- Dr C S Ramesh Babu, Former Professor and HOD of Anatomy, LLRM Medical College, Meerut, UP.
- Dr T S Roy, Former Professor and HOD of Anatomy, AIIMS, New Delhi.
- Dr Punita Manik, Professor and HOD of Anatomy, KGMU, Lucknow, UP.
- Dr Garima Sehgal, Additional Professor of Anatomy, KGMU, Lucknow, UP.
- Dr Ajai Nene, Professor and HOD of Anatomy, ESIC Medical College, Faridabad, Haryana.
- Dr Vipin Khade, Professor and HOD of Anatomy, Chirayu Medical College, Bhopal, MP.
- Dr Preeti Shrivastava, Associate Professor, NDMC Medical College, Delhi.

# Competency map: Head, neck and brain

Competency Code	Competency	Core (Y/N)	Chapter Nos.	Page Nos.
<b>HEAD AND NECK</b>				
<b>Topic: Skull Osteology</b>				
AN26.1	Demonstrate anatomical position of skull, Identify and locate individual skull bones in skull.	Y	2	13–15
AN26.2	Describe the features of norma frontalis, verticalis, occipitalis, lateralis and basalis.	Y	2	15–22
AN26.3	Describe cranial cavity, its subdivisions, foramina and structures passing through them.	Y	2	22–26
AN26.4	Describe morphological features of mandible.	Y	2	26–30
AN26.5	Describe features of typical and atypical cervical vertebrae (atlas and axis).	Y	2	43–45
AN26.6	Explain the concept of bones that ossify in membrane.	N	Refer General Anatomy, 4e by Vishram Singh, 76–77	
AN26.7	Describe the features of the 7th cervical vertebra.	N	2	45
<b>Topic: Scalp</b>				
AN27.1	Describe the layers of scalp, its blood supply, its nerve supply and	Y	3	47–51

AN27.2	Describe emissary veins with its role in spread of infection from extracranial route to intracranial venous sinuses.	Y	3	51
<b>Topic: Face and Parotid Region</b>				
AN28.1	Describe & demonstrate muscles of facial expression and their nerve supply.	Y	3	53–58
AN28.2	Describe sensory innervation of face.	Y	3	59–60
AN28.3	Describe & demonstrate origin /formation, course, branches /tributaries of facial vessels.	Y	3	60–61
AN28.4	Describe & demonstrate branches of facial nerve with distribution.	Y	8	114, 117
AN28.5	Describe cervical lymph nodes and lymphatic drainage of head, face and neck.	Y	16	242
AN28.6	Identify superficial muscles of face, their nerve supply and actions.	Y	3	53–56
AN28.7	Explain the anatomical basis of facial nerve palsy.	Y	3	58
AN28.8	Explain surgical importance of deep facial vein.	Y	3	61
AN28.9	Describe & demonstrate the parts, borders, surfaces, contents, relations and nerve supply of parotid gland with course of its duct and surgical importance.	Y	8	110–115
AN28.10	Explain the anatomical basis of Frey's syndrome.	N	8	115
<b>Topic: Posterior Triangle of Neck</b>				
AN29.1	Describe & demonstrate attachments, nerve supply, relations and actions of sternocleidomastoid.	Y	5	79–80
AN29.2	Explain anatomical basis of Erb's &	Y	Refer TB of	

	Klumpke's palsy.		Anatomy, Vol I, by Vishram Singh, 4e, P 56–57, 5	
AN29.3	Explain anatomical basis of wry neck.	N	5	80
AN29.4	Describe & demonstrate attachments of 1) inferior belly of omohyoid, 2) scalenus anterior, 3) scalenus medius & 4) levator scapulae. Infrahyoid muscles	N	6 , 12	88, 166
<b>Topic: Cranial Cavity</b>				
AN30.1	Describe the cranial fossae & identify related structures.	Y	21	314– 319
AN30.2	Describe & identify major foramina with structures passing through them.	Y	21	307– 311
AN30.3	Describe & identify dural folds & dural venous sinuses.	Y	21	311– 315
AN30.4	Describe clinical importance of dural venous sinuses.	Y	21	317, 319
AN30.5	Explain effect of pituitary tumours on visual pathway.	N	21 , 22	321– 322, 326– 333
<b>Topic: Orbit</b>				
AN31.1	Describe & identify extraocular muscles of eyeball.	Y	19	276, 279
AN31.2	Describe & demonstrate nerves and vessels in the orbit.	Y	19	279– 284
AN31.3	Describe anatomical basis of Horner's syndrome.	N	12	171
AN31.4	Enumerate components of lacrimal apparatus.	Y	3	64– 66
AN31.5	Explain the anatomical basis of oculomotor, trochlear and abducent nerve palsies along with	Y	22	334, 335, 336

	strabismus.			
<b>Topic: Anterior Triangle</b>				
AN32.1	Describe boundaries and subdivisions of anterior triangle.	Y	6	87–88
AN32.2	Describe & demonstrate boundaries and contents of muscular, carotid, digastric and submental triangles.	Y	6	88–93
<b>Topic: Temporal and Infratemporal Regions</b>				
AN33.1	Describe & demonstrate extent, boundaries and contents of temporal and infratemporal fossae.	Y	10	132–133
AN33.2	Describe & demonstrate attachments, direction of fibres, nerve supply and actions of muscles of mastication.	Y	10	133–135, 146–148
AN33.3	Describe & demonstrate articulating surface, type & movements of temporomandibular joint.	Y	10	141–146
AN33.4	Explain the clinical significance of pterygoid venous plexus.	Y	10	139
AN33.5	Describe the features of dislocation of temporomandibular joint.	N	10	146
<b>Topic: Submandibular Region</b>				
AN34.1	Describe & demonstrate the morphology, relations and nerve supply of submandibular salivary gland & submandibular ganglion.	Y	9	124–130
AN34.2	Describe the basis of formation of submandibular stones.	N	9	127
<b>Topic: Deep Structures in the Neck</b>				
AN35.1	Describe the parts, extent, attachments, modifications of deep cervical fascia.	Y	4	71–76
AN35.2	Describe & demonstrate location, parts, borders, surfaces, relations & blood supply of thyroid gland.	Y	11	153–158
AN35.3	Demonstrate & describe the origin,	Y	16	225–

	parts, course & branches subclavian artery.			228
AN35.4	Describe & demonstrate origin, course, relations, tributaries and termination of internal jugular & brachiocephalic veins.	Y	16	236–238
AN35.5	Describe and demonstrate extent, drainage & applied anatomy of cervical lymph nodes.	Y	16	240–242
AN35.6	Describe and demonstrate the extent, formation, relation & branches of cervical sympathetic chain.	Y	12	170–171
AN35.7	Describe the course and branches of IX, X, XI & XII nerve in the neck.	Y	22	333–339
AN35.8	Describe the anatomically relevant clinical features of Thyroid swellings.	N	11	158–159
AN35.9	Describe the clinical features of compression of subclavian artery and lower trunk of brachial plexus by cervical rib.	N	12 , 16	169, 231–232
AN35.10	Describe the pharyngeal spaces of neck.	N	4 , 14	76, 203
<b>Topic: Mouth, Pharynx and Palate</b>				
AN36.1	Describe the 1) morphology, relations, blood supply and applied anatomy of palatine tonsil 2) composition of soft palate.	Y	14	203–205, 209–211
AN36.2	Describe the components and functions of Waldeyer's lymphatic ring.	Y	14	198
AN36.3	Describe the boundaries and clinical significance of pyriform fossa.	N	14	196–197
AN36.4	Describe the anatomical basis of tonsillitis, tonsillectomy, adenoids and peri-tonsillar abscess.	N	14	205

AN36.5	Describe the clinical significance of Killian's dehiscence.	N	14	199
<b>Topic: Cavity of Nose</b>				
AN37.1	Describe & demonstrate features of nasal septum, lateral wall of nose, their blood supply and nerve supply.	Y	17	247–252

AN37.2	Describe location and functional anatomy of paranasal sinuses.	Y	17	252–255
AN37.3	Describe anatomical basis of sinusitis & maxillary sinus tumours.	N	17	255
<b>Topic: Larynx</b>				
AN38.1	Describe the morphology, identify structure of the wall, nerve supply, blood supply and actions of intrinsic and extrinsic muscles of the larynx.	Y	15	212–221
AN38.2	Describe the anatomical aspects of laryngitis.	N	15	221–222
AN38.3	Describe anatomical basis of recurrent laryngeal nerve injury.	N	15	221

<b>Topic: Tongue</b>				
AN39.1	Describe and demonstrate the morphology, nerve supply, embryological basis of nerve supply, blood supply, lymphatic drainage and actions of extrinsic and intrinsic muscles of tongue.	Y	13	184–191
AN39.2	Explain the anatomical basis of hypoglossal nerve palsy.	N	13 , 22	187–188, 339–340

<b>Topic: Organs of Hearing and Equilibrium</b>				
AN40.1	Describe and identify the parts, blood supply and nerve supply of external ear.	Y	18	258–260
AN40.2	Describe and demonstrate the	Y	18	262–

	boundaries, contents, relations and functional anatomy of middle ear and auditory tube.			267
AN40.3	Describe the features of internal ear.	N	18	267–271
AN40.4	Explain anatomical basis of otitis externa and otitis media.	N	18	260
AN40.5	Explain anatomical basis of myringotomy.	N	18	262
<b>Topic: Eyeball</b>				
AN41.1	Describe & demonstrate parts and layers of eyeball.	Y	19	284–289
AN41.2	Describe the anatomical aspects of cataract, glaucoma & central retinal artery occlusion.	N	19	288, 289, 290
AN41.3	Describe the position, nerve supply and actions of intraocular muscles.	N	19	282
<b>Topic: Back Region</b>				
AN42.1	Describe the contents of the vertebral canal.	Y	20	292–293
AN42.2	Describe & demonstrate the boundaries and contents of Suboccipital triangle.	Y	7	100–102
AN42.3	Describe the position, direction of fibres, relations, nerve supply, actions of semispinalis capitis and splenius capitis.	N	7	98, 99
AN43.1	Describe & demonstrate the movements with muscles producing the movements of atlantooccipital joint & atlantoaxial joint.	Y	7	106–108
AN43.2	Identify, describe and draw the microanatomy of pituitary gland, thyroid, parathyroid gland, tongue, salivary glands, tonsil, epiglottis, cornea, retina.	Y	11 , 13 , 19 , 21	158, 160–161, 184, 285, 287, 320
AN43.3	Identify, describe and draw microanatomy of olfactory epithelium,	N	18 , 19	269, 285,

	eyelid, lip, sclero-corneal junction, optic nerve, cochlea-organ of corti, pineal gland.			287
AN43.4	Describe the development and developmental basis of congenital anomalies of face, palate, tongue, branchial apparatus, pituitary gland, thyroid gland & eye.	Y	Refer TB of Embryology, 3e, by Vishram Singh	
AN43.5	Demonstrate- 1) Testing of muscles of facial expression, extraocular muscles, muscles of mastication, 2) Palpation of carotid arteries, facial artery, superficial temporal artery, 3) Location of internal and external jugular veins, 4) Location of hyoid bone, thyroid cartilage and cricoid cartilage with their vertebral levels.	Y	3 , 4 , 6 , 10 , 19	57, 70, 91, 148, 278
AN43.6	Demonstrate surface projection of Thyroid gland, Parotid gland and duct, Pterion, Common carotid artery, Internal jugular vein, Subclavian vein, External jugular vein, Facial artery in the face & accessory nerve.	N	30	402–407
AN43.7	Identify the anatomical structures in 1) Plain x-ray skull, 2) AP view and lateral view 3) Plain x-ray cervical spine-AP and lateral view 4) Plain x-ray of paranasal sinuses.	Y	7	103
AN43.8	Describe the anatomical route used for carotid angiogram and vertebral angiogram.	N	Refer TB of Clinical Neuroanatomy, 4e, by Vishram Singh, Ch 15	185–186
AN43.9	Identify anatomical structures in carotid angiogram and vertebral angiogram.	N	Refer TB of Clinical Neuroanatomy, 4e, by Vishram Singh, Ch 15	185–186

## BRAIN

### Topic: Meninges and CSF

AN56.1	Describe & identify various layers of meninges with its extent & modifications.	Y	21 , 23	311–315
				350
AN56.2	Describe circulation of CSF with its applied anatomy.	Y	23	352–353

### Topic: Spinal Cord

AN57.1	Identify external features of spinal cord.	Y	20	295
AN57.2	Describe extent of spinal cord in child and adult with its clinical implication.	Y	20	294–295
AN57.3	Draw & label transverse section of spinal cord at mid-cervical & mid-thoracic level.	Y	20	297
AN57.4	Enumerate ascending & descending tracts at mid thoracic level of spinal cord.	Y	20	298 - 300
AN57.5	Describe anatomical basis of syringomyelia.	N	20	301

### Topic: Medulla Oblongata

AN58.1	Identify external features of medulla oblongata.	Y	24	355
AN58.2	Describe transverse section of medulla oblongata at the level of 1) pyramidal decussation, 2) sensory decussation 3) ION.	Y	24	355, 356–357
AN58.3	Enumerate cranial nerve nuclei in medulla oblongata with their functional group.	Y	24	360
AN58.4	Describe anatomical basis & effects of medial & lateral medullary syndrome.	N	24	367

### Topic: Pons

AN59.1	Identify external features of pons.	Y	24	358
AN59.2	Draw & label transverse section of pons at the upper and lower level.	Y	24	359
AN59.3	Enumerate cranial nerve nuclei in pons	Y	24	360

	with their functional group.			
<b>Topic: Cerebellum</b>				
AN60.1	Describe & demonstrate external & internal features of cerebellum.	Y	25	365–367
AN60.2	Describe connections of cerebellar cortex and intracerebellar nuclei.	Y	25	367–368
AN60.3	Describe anatomical basis of cerebellar dysfunction.	N	25	368
<b>Topic: Midbrain</b>				
AN61.1	Identify external & internal features of midbrain.	Y	24	360–361
AN61.2	Describe internal features of midbrain at the level of superior & inferior colliculus.	Y	24	361
AN61.3	Describe anatomical basis & effects of Benedikt's and Weber's syndrome.	N	24	362
<b>Topic: Cranial Nerve Nuclei and Cerebral Hemispheres</b>				
AN62.1	Enumerate cranial nerve nuclei with its functional component.	Y	24	363
AN62.2	Describe & demonstrate surfaces, sulci, gyri, poles, & functional areas of cerebral hemisphere.	Y	27	378–382
AN62.3	Describe the white matter of cerebrum.	Y	27	382–385
AN62.4	Enumerate parts & major connections of basal ganglia & limbic lobe.	Y	28	388–392
AN62.5	Describe boundaries, parts, gross relations, major nuclei and connections of dorsal thalamus, hypothalamus, epithalamus, metathalamus and subthalamus.	Y	26	371–375
AN62.6	Describe & identify formation, branches & major areas of distribution of circle of Willis.	Y	29	394–400
<b>Topic: Ventricular System</b>				

AN63.1	Describe & demonstrate parts, boundaries &	Y	25 ,	368–
--------	--	---	------	------

	features of IIIrd, IVth & lateral ventricle.		26 , 27	369
				375– 376
				385– 386
AN63.2	Describe anatomical basis of congenital hydrocephalus.	N	23	353

---

# List of Illustrations

---

**FIG. 1.1** ■ Change in position of face in relation to cranium during evolution. The face is located in front of cranium in dog, below and in front of cranium in monkey, and below the anterior part of cranium in humans. Note that the size of jaws is inversely proportional to the size of cranium. C, cranium; F, face.

**FIG. 1.2** ■ Regions of the head. The aesthetic regions of face are marked by yellow colour.

**FIG. 1.3** ■ Surface landmarks on the lateral aspect of the head.

**FIG. 1.4** ■ Lateral view of right auricle: (A) schematic diagram and (B) actual picture.

**FIG. 1.5** ■ Frontal view of the left eye.

**FIG. 1.6** ■ Surface landmarks on frontal aspect of the head.

**FIG. 1.7** ■ Frontal view of the lips: (A) schematic diagram and (B) actual picture.

**FIG. 1.8** ■ Features of the oral cavity and oropharynx.

**FIG. 1.9** ■ The basic plan of the neck in cross-section: (A) disposition of deep cervical fascia and delineation of compartments of neck (B) schematic diagram showing compartments of the neck.

**FIG. 1.10** ■ Cross-section of the neck showing anatomical details of various compartments of neck. S, spinal cord; C, cervical vertebra.

**FIG. 1.11** ■ Basic layout of structure of the neck.

**FIG. 1.12** ■ Surface landmarks in anterior median and lateral regions of the neck.

**FIG. 1.13** ■ Surface landmarks in posterior region of the neck.

**FIG. 1.14** ■ Location of anterior and posterior triangles of the side of neck.

**FIG. 2.1** ■ Skull: (A) anterior/frontal view and (B) lateral view.

**FIG. 2.2** ■ Skull showing cranial skeleton (*orange colour*) and facial skeleton (*violet colour*). (A) Frontal view; (B) lateral view.

**FIG. 2.3** ■ Anatomical position of the skull.

**FIG. 2.4** ■ Norma verticalis.

**FIG. 2.5** ■ Norma occipitalis.

**FIG. 2.6** ■ Norma frontalis. P = prosthion

**FIG. 2.7** ■ Norma lateralis.

**FIG. 2.8** ■ Surface marking of pterion.

**FIG. 2.9** ■ Pterion and extradural haematoma. (A) Relationship of anterior division middle meningeal artery to pterion; (B) extradural haematoma.

**FIG. 2.10** ■ Norma basalis.

**FIG. 2.11** ■ Enlarged view of base of skull to show the features lying in the same imaginary transverse lines.

**FIG. 2.12** ■ Foetal skull to show the location of fontanelles: (A) lateral aspect and (B) superior aspect.

**FIG. 2.13** ■ Whole mandible: (A) anterior view and (B) posterior view. Figure in the inset above shows the shape of horse shoe.

**FIG. 2.14** ■ Right half of the mandible: (A) external aspect and (B) internal aspect.

**FIG. 2.15** ■ Muscles attached to the mandible. (A) Lateral surface of right half of the mandible; (B) inner surface of left half of the mandible. GG, genioglossus; GH, geniohyoid.

**FIG. 2.16** ■ Attachment of ligaments and nerves related to the mandible. (A) Lateral surface of the right half of the mandible; (B) medial surface of the left half of the mandible.

**FIG. 2.17** ■ Sites of the mandibular fracture: (A) neck of the mandible; (B) angle of the mandible; and (C) canine region.

**FIG. 2.18** ■ Age-related changes in the mandible.

**FIG. 2.19** ■ Right maxilla: (A) lateral aspect showing orbital, infratemporal and anterior surfaces and (B) medial aspect showing nasal surface and maxillary hiatus. ZP = Zygomatic process, JC = jugular crest.

**FIG. 2.20** ■ Processes of left maxilla.

**FIG. 2.21** ■ Bilateral fractures of the maxilla: (A) Le Fort I; (B) Le Fort II; and (C) Le Fort III.

**FIG. 2.22** ■ Right temporal bone: external aspect. The figure in the inset on the right shows parts of temporal bone. Sq. P = squamous part in bone colour, PM = petromastoid part in red colour, TP = tympanic part in blue colour, SP = styloid part in green colour.

**FIG. 2.23** ■ Right parietal bone: (A) external surface and (B) internal surface.

**FIG. 2.24** ■ Zygomatic bone (right side).

**FIG. 2.25** ■ Frontal bone: (A) external aspect and (B) inferior aspect.

**FIG. 2.26** ■ Occipital bone: (A) external surface and (B) internal surface.

**FIG. 2.27** ■ Sphenoid bone: (A ) superior aspect and (B ) posterior aspect. The figure in the inset shows the butterfly for its resemblance with sphenoid bone. LW = lesser wing, GW = greater wing, PP = pterygoid process, B = body

**FIG. 2.28** ■ Ethmoid bone. (A ) Location of ethmoid in relation to nasal cavity, orbits, and maxillary sinuses; (B ) superior view of ethmoid bone.

**FIG. 2.29** ■ Palatine bone: (A ) medial aspect and (B ) posterior aspect of two palatine bones together.

**FIG. 2.30** ■ Vomer in relation to sphenoid and palatine bones. Note the formation of vomerovaginal and palatovaginal canals.

**FIG. 2.31** ■ Hyoid bone (anterior view). (A ) Parts of hyoid bone; (B ) muscle attachments.

**FIG. 2.32** ■ Typical cervical vertebra (superior aspect); inset on the right side shows the costal and transverse elements of the transverse process.

**FIG. 2.33** ■ Atypical cervical vertebrae. (A ) Atlas vertebra (superior aspect); (B ) axis vertebra (posterosuperior aspect); and (C ) 7th cervical vertebra (superior aspect).

**FIG. 3.1** ■ Extent of the scalp.

**FIG. 3.2** ■ Layers of the scalp.

**FIG. 3.3** ■ Occipitofrontalis muscle.

**FIG. 3.4** ■ Sagittal section of the skull cap and overlying soft tissues. Note the migration of blood from fourth layer of the scalp (layer of loose areolar tissue) to the scanty subcutaneous tissue over orbicularis oculi.

**FIG. 3.5** ■ Sensory supply of the scalp (shown in left half only).

**FIG. 3.6** ■ Arterial supply of the scalp. The area enclosed by blue dotted line shows the temporal flap.

**FIG. 3.7** ■ Layers of the soft tissue in the temple.

**FIG. 3.8** ■ Lines of cleavage in the head and neck region: (A ) front view and (B ) lateral view.

**FIG. 3.9** ■ Muscles of the facial expression: (A ) sites of bony attachment and (B ) position in the face. Masseter and temporalis (muscles of mastication) are also shown. T, temporalis.

**FIG. 3.10** ■ Orbicularis oris muscle: (A ) arrangement of fibres and (B ) formation of modiolus.

**FIG. 3.11** ■ Buccinator muscle: (A ) origin and (B ) location in the face and insertion.

**FIG. 3.12** ■ Motor supply of the muscles of facial expression. Auricular muscles are not shown because they have no role in the facial expression in human beings. CF, cervicofacial trunk; MP, mastoid process; TF,

temporofacial trunk.

**FIG. 3.13** ■ Lateral view of the face illustrating the simple method of remembering the terminal branches of the facial nerve.

**FIG. 3.14** ■ Bell's palsy on the right side. Note the facial asymmetry (right side appears to be pulled on the left side).

**FIG. 3.15** ■ Sensory innervation of the face. Note trigeminal and spinal fields. V1, ophthalmic division of trigeminal nerve; V2, maxillary division of trigeminal nerve; V3, mandibular division of trigeminal nerve.

**FIG. 3.16** ■ Sensory nerves of the face.

**FIG. 3.17** ■ Arterial supply of the face. 1, zygomaticotemporal; 2, zygomaticofacial; 3, infraorbital; 4, palpebral branch of lacrimal artery.

**FIG. 3.18** ■ Venous drainage of the face.

**FIG. 3.19** ■ Dangerous area of the face.

**FIG. 3.20** ■ Lymphatic drainage of the scalp and face.

**FIG. 3.21** ■ Free margins of the eyelids.

**FIG. 3.22** ■ Structure of the eyelid (sagittal section of upper eyelid).

**FIG. 3.23** ■ Tarsal plates and palpebral fascia.

**FIG. 3.24** ■ Features of the palpebral fissure.

**FIG. 3.25** ■ Lacrimal apparatus.

**FIG. 3.26** ■ Relations of the lacrimal sac.

**FLOWCHART 3.1** ■ Parasympathetic pathway of lacrimal gland.

**FLOWCHART 3.2** ■ Sympathetic pathway of lacrimal gland.

**FIG. 4.1** ■ Dermatomes of the head and neck.

**FIG. 4.2** ■ Origin and insertion of the platysma.

**FIG. 4.3** ■ Decussation of the anterior fibres of platysma. Also note the location of anterior jugular veins and jugular venous arch.

**FIG. 4.4** ■ Cutaneous nerves of the neck.

**FIG. 4.5** ■ Superficial veins of the neck.

**FIG. 4.6** ■ Superficial cervical lymph nodes.

**FIG. 4.7** ■ Ring of superficial cervical lymph nodes at the junction of the head and neck.

**FIG. 4.8** ■ Vertical extent and disposition of the three layers of the deep cervical fascia. Buccopharyngeal fascia is also shown. Note the continuity of fascial spaces of the neck into the mediastinum.

**FIG. 4.9** ■ Diagrammatic transverse section through neck at the level of the 6th cervical vertebra to show the horizontal disposition of the three layers of deep cervical fascia.

**FIG. 4.10** ■ Investing layer of the deep cervical fascia enclosing two glands:

(**A**) parotid gland and (**B**) submandibular gland.

**FIG. 4.11** ■ (**A**) Suprasternal space (of Burns) and (**B**) Investing layer of the deep cervical fascia enclosing supraclavicular space.

**FIG. 4.12** ■ Vertical disposition of pretracheal fascia enclosing thyroid gland.

**FIG. 4.13** ■ Retropharyngeal space.

**FIG. 4.14** ■ Carotid sheath: (**A**) surface view and (**B**) sectional view.

**FIG. 5.1** ■ Surface landmarks on the side of the neck.

**FIG. 5.2** ■ Boundaries and triangles on the side of the neck. The quadrilateral shape of the side of the neck with posterior and anterior triangles can be well appreciated by the figure in the inset.

**FIG. 5.3** ■ Origin and insertion of the sternocleidomastoid muscle.

**FIG. 5.4** ■ Actions of the sternocleidomastoid muscle. (**A**) Ipsilateral flexion and contralateral rotation when acting alone. (**B**) Flexion of head, when acting together.

**FIG. 5.5** ■ Torticollis/wry neck.

**FIG. 5.6** ■ A Boundaries and floor of the posterior triangle. B Structures piercing the roof of the posterior triangle.

**FIG. 5.7** ■ Subdivisions and main contents of the posterior triangle.

**FIG. 5.8** ■ Schematic diagram showing the floor and contents of the right posterior triangle.

**FIG. 5.9** ■ Course of spinal accessory nerve right through sternocleidomastoid muscle. Note the relation of lymph nodes to this nerve.

**FIG. 5.10** ■ Cutaneous branches of the cervical plexus. Note the location of 'nerve point of the neck' (*dotted red circle*).

**FIG. 5.11** ■ Branches arising from cervical part (roots of trunks) of brachial plexus. NS, nerve to subclavius; SS, suprascapular nerve.

**FIG. 6.1** ■ Schematic diagram of anterior median region of the neck showing suprahyoid and infrahyoid area.

**FIG. 6.2** ■ Structures in the anterior midline of the neck.

**FIG. 6.3** ■ Boundaries and subdivisions of the right anterior triangle of neck. The subdivisions are labelled in *bold colour*.

**FIG. 6.4** ■ Boundaries and contents of the submental triangle.

**FIG. 6.5** ■ Digastric (submandibular) triangle: (**A**) boundaries and floor; (**B**) boundaries and contents.

**FIG. 6.6** ■ Carotid triangle: (**A**) boundaries and floor; (**B**) boundaries and contents.

**FIG. 6.7** ■ Formation and distribution of the ansa cervicalis.

- FIG. 6.8** ■ Location and relations of the ansa cervicalis.
- FIG. 6.9** ■ Origin and insertion of the infrahyoid muscles.
- FIG. 7.1** ■ Dissection of suboccipital region showing superficial structures on the left side and deep structures on the right side.
- FIG. 7.2** ■ Ligamentum nuchae.
- FIG. 7.3** ■ Origin and insertion of the trapezius. The latissimus dorsi is also shown.
- FIG. 7.4** ■ Origin and insertion of the splenius capitis. The part of splenius cervicis is also seen.
- FIG. 7.5** ■ Origin and insertion of the longissimus capitis.
- FIG. 7.6** ■ Origin and insertion of the semispinalis capitis.
- FIG. 7.7** ■ Schematic posterior view of the skull, showing bony boundaries of suboccipital region and sites of the muscular attachments.
- FIG. 7.8** ■ Suboccipital muscles. Boundaries and floor of the suboccipital triangle are also seen.
- FIG. 7.9** ■ Boundaries and contents of the suboccipital triangle.
- FIG. 7.10** ■ Relationship of the third part of vertebral artery and 1st cervical nerve to the atlas vertebral as seen from the superior aspect.
- FIG. 7.11** ■ Cervical vertebral column: (A) schematic diagram and (B) lateral radiograph. **AN 43.7**
- FIG. 7.12** ■ Typical cervical vertebra (superior aspect).
- FIG. 7.13** ■ Purely schematic diagram to show secondary cartilaginous joints (symphyses) between the vertebral bodies.
- FIG. 7.14** ■ Purely schematic diagram to show anterior longitudinal ligament.
- FIG. 7.15** ■ Purely schematic diagram to show posterior longitudinal ligament.
- FIG. 7.16** ■ Zygapophyseal joints between the superior and inferior articular processes of adjacent vertebrae.
- FIG. 7.17** ■ Intervertebral syndesmosis. Note the location of ligamenta flava (anterior aspect).
- FIG. 7.18** ■ Posterior view of the ligaments connecting the axis with occipital bone. The superior band of cruciform ligament is cut.
- FIG. 7.19** ■ Median atlanto-axial articulation.
- FIG. 7.20** ■ Median sagittal section through the foramen magnum and 1st–3rd cervical vertebrae.
- FIG. 7.21** ■ Atlanto-occipital joint.
- FIG. 7.22** ■ Atlanto-axial joint (includes one median atlantoaxial joint and

two lateral atlantoaxial joints).

**FIG. 7.23** ■ Hangman's fracture.

**FIG. 7.24** ■ Executive hanging: (A) hanging; (B) fracture of odontoid process; and (C) rupture of transverse ligament of atlas.

**FIG. 8.1** ■ Main features of the parotid region.

**FIG. 8.2** ■ Parotid bed and location of the parotid gland.

**FIG. 8.3** ■ Parotid capsule.

**FIG. 8.4** ■ Horizontal section through parotid gland showing its relations and the structures passing through it. The inset figure shows borders and surfaces of the parotid gland. SG, styloglossus muscle; SH, stylohyoid muscle; SP, stylopharyngeus muscle.

**FIG. 8.5** ■ The structures emerging at the periphery of the parotid gland.

**FIG. 8.6** ■ The structures traversing the parotid gland: (A ) facial nerve; (B ) retromandibular vein; and (C ) external carotid artery.

**FIG. 8.7** ■ Patey's facio-venous (neurovenous) plane in the parotid gland. The retromandibular vein is not shown for clarity. (A ) Two lobes joined by an isthmus; (B ) superficial lobe is removed after dividing on isthmus leaving facial nerve and its branches intact.

**FIG. 8.8** ■ Sites of origin and termination of the parotid duct.

**FIG. 8.9** ■ Course of the parotid duct. Also note the structures pierced by it during its course from the parotid gland to the vestibule of the mouth.

**FIG. 8.10** ■ Extracranial course of the facial nerve. CF, cervicofacial trunk; TF, temporofacial trunk; T, Z, B, MM, and C, represent temporal, zygomatic, buccal, marginal mandibular, and cervical branches of the facial nerve respectively.

**FLOWCHART 8.1** ■ The secretomotor supply of parotid gland.

**FIG. 9.1** ■ Structures seen in the superficial dissection of the right submandibular region.

**FIG. 9.2** ■ Origin and insertion of the digastric muscle.

**FIG. 9.3** ■ Important deep relations of the posterior belly of the digastric muscle.

**FIG. 9.4** ■ Origin and insertion of the stylohyoid muscle.

**FIG. 9.5** ■ Origin and insertion of the mylohyoid muscle (as seen from below).

**FIG. 9.6** ■ Origin and insertion of the geniohyoid muscle.

**FIG. 9.7** ■ Origin and insertion of the hyoglossus muscle.

**FIG. 9.8** ■ Superficial relations of the hyoglossus muscle.

**FIG. 9.9** ■ Origin and insertion of the styloglossus muscle.

**FIG. 9.10 ■** Origin and insertion of the genioglossus muscle.

**FIG. 9.11 ■** Features of the internal aspect of the right half of the body of mandible.

**FIG. 9.12 ■** Left submandibular and sublingual salivary glands.

**FIG. 9.13 ■** Schematic horizontal section through submandibular region showing the parts of submandibular gland. The sublingual salivary gland is also seen. Note the relationship of the sublingual gland with the deep part of the submandibular gland and submandibular duct.

**FIG. 9.14 ■** Capsule of the superficial part of the submandibular gland.

**FIG. 9.15 ■** Relations of the superficial (inferior) surface of submandibular salivary gland. The relations of anterior part of the medial (deep) surface are also seen.

**FIG. 9.16 ■** Relations of the lateral surface.

**FIG. 9.17 ■** Relations of the medial (deep) surface of the submandibular gland.

**FIG. 9.18 ■** Location and relations of the deep part of submandibular gland and submandibular ganglion. Red circle of broken line represents the superficial part of the submandibular gland.

**FIG. 9.19 ■** Submandibular and sublingual ducts.

**FIG. 9.20 ■** Bimanual palpation of the submandibular salivary gland.

**FIG. 9.21 ■** Roots and branches of submandibular ganglion.

**FIG. 9.22 ■** Planes of the submandibular region: (A ) first muscular plane; (B ) second muscular plane; (C ) third surgical (muscular) plane; and (D ) fourth surgical (muscular) plane.

**FLOWCHART 9.1 ■** Parasympathetic (secretomotor) supply of submandibular and sublingual glands.

**FIG. 10.1 ■** Communication (*arrows*) between infratemporal and temporal fossae.

**FIG. 10.2 ■** Boundaries of the infratemporal fossa.

**FIG. 10.3 ■** Schematic diagram to show the boundaries and communications of the infratemporal fossa.

**FIG. 10.4 ■** Origin and insertion of the lateral pterygoid muscle.

**FIG. 10.5 ■** Relation of the lateral pterygoid muscle.

**FIG. 10.6 ■** Origin and insertion of the medial pterygoid muscle.

**FIG. 10.7 ■** Superficial relations of the medial pterygoid muscle.

**FIG. 10.8 ■** Branches of the maxillary artery. L, lingual branch.

**FIG. 10.9 ■** Course and distribution of the mandibular nerve. SM, submandibular ganglion.

**FIG. 10.10** ■ Functional components of the chorda tympani nerve.

**FIG. 10.11** ■ Origin, course, and relations of the chorda tympani nerve.

**FIG. 10.12** ■ Otic ganglion and its connections.

**FIG. 10.13** ■ Articular surfaces of the temporomandibular joint.

**FIG. 10.14** ■ Parts of the intra-articular disc.

**FIG. 10.15** ■ Ligaments of the temporomandibular joint: (A ) fibrous capsule and lateral ligament; and (B ) accessory ligaments.

**FIG. 10.16** ■ Relations of the sphenomandibular ligament: (A ) lateral relations and (B ) medial relations. It also shows medial relations of temporomandibular joint as seen in coronal section.

**FIG. 10.17** ■ ‘Swing’ formed by the mandible and accessory ligaments of TMJs.

**FIG. 10.18** ■ Movements of the lower jaw related to temporomandibular joint to show the opening and closing of the mouth. Note the changing relation of the condyle of the mandible.

**FIG. 10.19** ■ Temporomandibular joint: (A ) normal and (B ) in anterior dislocation.

**FIG. 10.20** ■ Muscles of mastication producing movements of the temporomandibular joint. The *arrows* indicate the direction of their actions. Chief muscles of mastication are labelled in bold.

**FIG. 10.21** ■ Origin and insertion of the temporalis muscle.

**FIG. 10.22** ■ Origin and insertion of the masseter muscle.

**FIG. 10.23** ■ Boundaries of the pterygopalatine fossa.

**FIG. 10.24** ■ Origin, course, and branches of the maxillary nerve.

**FIG. 10.25** ■ Pterygopalatine ganglion, its roots and branches.

**FLOWCHART 10.1** ■ Communications of the infratemporal fossa.

**FIG. 11.1** ■ Location of the thyroid gland.

**FIG. 11.2** ■ Parts and extent of the thyroid gland.

**FIG. 11.3** ■ Capsules of the thyroid gland.

**FIG. 11.4** ■ Relations of the lateral lobe of the thyroid gland: (A ) upward extension of the thyroid lobe and muscles attached to the oblique line of the thyroid cartilage; (B ) the apex is sandwiched between the inferior constrictor and sternothyroid.

**FIG. 11.5** ■ Transverse section of the anterior part of the neck at the level of thyroid isthmus showing relations of the thyroid gland.

**FIG. 11.6** ■ Medial relations of the lateral lobe of the thyroid gland. The figure also shows intimate relationship of the external and recurrent laryngeal nerves with the superior and inferior thyroid arteries, respectively.

**FIG. 11.7** ■ Arterial supply of the thyroid gland.

**FIG. 11.8** ■ Variable relationship of recurrent laryngeal nerve with the inferior thyroid artery.

**FIG. 11.9** ■ Venous drainage of the thyroid gland.

**FIG. 11.10** ■ Lymphatic drainage of the thyroid gland.

**FIG. 11.11** ■ Microscopic structure of the thyroid gland.

**FIG. 11.12** ■ Massive enlargement of the thyroid gland.

**FIG. 11.13** ■ Development of the thyroid gland: (A ) different stages in the development; (B ) shows the path taken by thyroglossal duct as it migrates inferiorly.

**FIG. 11.14** ■ Location of the parathyroid glands: (A ) posterior aspect of the thyroid gland; (B ) section through thyroid lobe along with its capsule.

**FIG. 11.15** ■ Hand spasm in tetany.

**FIG. 11.16** ■ Development of the parathyroid gland: sites of development and final positions taken by them. III= Third pharyngeal pouch, IV= fourth pharyngeal pouch.

**FIG. 11.17** ■ Tracheostomy.

**FIG. 12.1** ■ Bony features in the pre- and paravertebral regions and the root of the neck.

**FIG. 12.2** ■ Attachments of the anterior vertebral muscles.

**FIG. 12.3** ■ Attachment of the longus capitis muscle.

**FIG. 12.4** ■ Attachments of the scalenus posterior muscle.

**FIG. 12.5** ■ Attachments of the scalenus medius muscle.

**FIG. 12.6** ■ Attachments of the scalenus anterior muscle.

**FIG. 12.7** ■ Schematic sagittal section to show the anterior and posterior relations of the scalenus anterior muscle.

**FIG. 12.8** ■ Scalene triangle.

**FIG. 12.9** ■ Boundaries and contents of right scalenovertebral triangle (triangle of vertebral artery).

**FIG. 12.10** ■ Position of rami of cervical spinal nerve in relation to prevertebral muscles.

**FIG. 12.11** ■ Cervical plexus: A. with loops and cutaneous branches, B. with its communicating branches.

**FIG. 12.12** ■ Phrenic nerve: A. Formation, course and distribution of phrenic nerve proper, B. Accessory phrenic nerve.

**FIG. 12.13** ■ Cervical sympathetic trunk and its branches.

**FIG. 12.14** ■ Horner syndrome (left side).

**FIG. 12.15** ■ Deep structures at the root of the neck.

**FIG. 12.16** ■ Transverse section of the root of neck showing relationship of various structures in this region.

**FIG. 13.1** ■ Subdivisions of the oral cavity as seen in its coronal section.

**FIG. 13.2** ■ Schematic diagram showing approximate age of eruption of teeth: (A) deciduous teeth; (B) permanent teeth. The teeth are numbered according to Zsigmondy system.

**FIG. 13.3** ■ Parts of the tooth: (A) extracted upper right canine tooth; (B) clinical and anatomical crowns.

**FIG. 13.4** ■ Structure of the tooth.

**FIG. 13.5** ■ Nerve supply of the teeth. L, lingual nerve.

**FIG. 13.6** ■ Types of the permanent teeth (upper and lower teeth) of the right side.

**FIG. 13.7** ■ Dental terminology used for surfaces. 1, central incisor; 2, lateral incisor; 3, canine; 4, 1st premolar; 5, 2nd premolar; 6, 1st molar; 7, 2nd molar; 8, 3rd molar.

**FIG. 13.8** ■ (A) Development of teeth; (B) Eruption of tooth. The figures in the inset show formation of dental lamina (a), and tooth buds of all deciduous teeth (b).

**FIG. 13.9** ■ The fauces and its isthmus seen through the widely open mouth.

**FIG. 13.10** ■ Sublingual region seen when the tongue is turned upwards. Features on inferior surface of the tongue are also seen.

**FIG. 13.11** ■ Features on the dorsal surface of the tongue.

**FIG. 13.12** ■ Characteristic features of different types of lingual papillae: (A) filiform; (B) fungiform; and (C) vallate.

**FIG. 13.13** ■ Features on the ventral (inferior) surface of the tongue and floor of the mouth.

**FIG. 13.14** ■ Coronal section of the tongue showing arrangement of intrinsic and extrinsic muscles of the tongue.

**FIG. 13.15** ■ Extrinsic muscles of the tongue.

**FIG. 13.16** ■ Movements of the tongue: (A) protrusion of the tongue; (B) elevation, depression, and retraction.

**FIG. 13.17** ■ Effect of paralysis of the hypoglossal nerve. (A) Paralysis of the genioglossus on the left side. (B) Deviation of the tongue on the left side, that is, on the paralysed side.

**FIG. 13.18** ■ Arterial supply of the tongue. FA, facial artery; EC, external carotid artery.

**FIG. 13.19** ■ Lymphatic drainage of the tongue: (A) course and direction of

apical, marginal, and basal lymph vessels; (**B**) course and direction of central lymph vessels. Figure in the inset shows area (*in red*) having bilateral lymphatic drainage.

**FIG. 13.20** ■ Nerve supply of the tongue. Right half of the figure shows motor supply and left half shows sensory supply.

**FIG. 13.21** ■ Nerves carrying taste sensations from the tongue.

**FIG. 13.22** ■ Development of the tongue: (**A**) appearance of four swellings in the floor of primitive pharynx; (**B**) formation of anterior two-third by the growth and fusion of two lingual swellings and posterior one-third by the growth and fusion of cranial part of the hypobranchial eminence.

**FIG. 14.1** ■ Sagittal section through the nose, mouth, pharynx, and larynx.

**FIG. 14.2** ■ Pathways for food (*red arrow*) and air (*green arrow*) through the pharynx.

**FIG. 14.3** ■ Subdivisions of the pharynx.

**FIG. 14.4** ■ Pharynx opened from behind showing features in the anterior walls of the nasopharynx, oropharynx, and laryngopharynx.

**FIG. 14.5** ■ Boundaries of the oropharyngeal isthmus.

**FIG. 14.6** ■ Schematic coronal section through larynx showing location and boundaries of the piriform fossa.

**FIG. 14.7** ■ Structure of the pharyngeal wall.

**FIG. 14.8** ■ Waldeyer's ring (an interrupted 'circle of tonsils' at the upper end of the respiratory and alimentary tracts).

**FIG. 14.9** ■ Overlapping arrangement of the constrictor muscles of the pharynx. The figure in the inset shows flowerpot arrangement of the constrictors. SC, superior constrictor; MC, middle constrictor, IC, inferior constrictor.

**FIG. 14.10** ■ Origin and insertion of constrictors of the pharynx.

**FIG. 14.11** ■ Killian's dehiscence.

**FIG. 14.12** ■ Pharyngeal pouch (diverticulum): (**A**) schematic diagram; (**B**) as seen in barium swallow.

**FIG. 14.13** ■ Structures passing through the gaps in the pharyngeal wall.

**FIG. 14.14** ■ Origin and insertion of the longitudinal muscles of the pharynx. SC, superior constrictor; MC, middle constrictor; IC, inferior constrictor.

**FIG. 14.15** ■ Stages of swallowing. A. First stage, B. Second stage, C, third stage.

**FIG. 14.16** ■ Parapharyngeal or lateral pharyngeal space.

**FIG. 14.17** ■ Horizontal section through tonsillar fossa showing medial and

lateral surfaces of the tonsil and tonsillar bed.

**FIG. 14.18** ■ Horizontal section through right palatine tonsil showing structures deep to its lateral surface.

**FIG. 14.19** ■ Arteries supplying the tonsil.

**FIG. 14.20** ■ Histological structure of the palatine tonsil.

**FIG. 14.21** ■ Bony and cartilaginous parts, isthmus, tympanic and pharyngeal ends of the pharyngotympanic tube.

**FIG. 14.22** ■ Oral aspect of the hard palate.

**FIG. 14.23** ■ Microscopic features (composition) of soft palate.

**FIG. 14.24** ■ Muscles of the soft palate.

**FIG. 14.25** ■ Origin and course of the tensor palati muscles and formation of the palatine aponeurosis by the expansion of their tendons underneath the hard palate behind the palatine crest.

**FIG. 14.26** ■ Development of the palate: (**A**) separation of the nasal cavities from each other and from oral cavity; (**B**) embryological subdivisions of the palate and their source of development.

**FIG. 15.1** ■ Principal cartilages of the larynx.

**FIG. 15.2** ■ Attachments of the muscles and ligaments on the thyroid cartilage: (**A**) on the posterior surface; (**B**) on the outer surface and posterior border of the lamina.

**FIG. 15.3** ■ Skeleton of the larynx: (**A**) anterior view; (**B**) posterior view; and (**C**) lateral view.

**FIG. 15.4** ■ Joints of the larynx.

**FIG. 15.5** ■ Sagittal section of the larynx showing ligaments and membranes. Note the location of quadrangular and cricovocal membranes.

**FIG. 15.6** ■ Intrinsic muscles of the larynx: (**A**) lateral view; (**B**) posterior view; and (**C**) direction of pull of some intrinsic muscles. VP, vocal process of arytenoid.

**FIG. 15.7** ■ Action of the cricothyroid muscle.

**FIG. 15.8** ■ Origin and insertion of the vocalis muscle.

**FIG. 15.9** ■ Heimlich manoeuvre. Figure in the inset shows the position of hands in the epigastric region of the victim.

**FIG. 15.10** ■ Coronal section of the laryngeal cavity showing its subdivisions. A, vestibule; B, ventricle of the larynx; C, infraglottic compartment.

**FIG. 15.11** ■ Laryngocele.

**FIG. 15.12** ■ Variations in the size and shape of rima glottidis during different movements of the vocal cords.

**FIG. 15.13** ■ Vocal nodules.

**FIG. 15.14** ■ Laryngoscopic view of the laryngeal cavity during moderate respiration. Note that rima glottidis is widely open. (A ) Schematic diagram; (B ) and (C ) actual photographs.

**FIG. 16.1** ■ Arteries supplying the head and neck.

**FIG. 16.2** ■ Origin of the subclavian arteries. Note that the right subclavian artery arises from the brachiocephalic trunk, whereas the left subclavian artery arises directly from the arch of aorta.

**FIG. 16.3** ■ Parts of the subclavian artery.

**FIG. 16.4** ■ Schematic diagram to show the relations of right subclavian artery.

**FIG. 16.5** ■ Subclavian artery pulse.

**FIG. 16.6** ■ Branches of the right and left subclavian arteries.

**FIG. 16.7** ■ Course and parts of the vertebral artery.

**FIG. 16.8** ■ Subclavian steal syndrome.

**FIG. 16.9** ■ Schematic diagram showing origin, course, and branches of the costocervical trunk.

**FIG. 16.10** ■ Curved course of the external carotid artery. Note the relationship of the external carotid with the internal carotid arteries.

**FIG. 16.11** ■ Branches of the external carotid artery.

**FIG. 16.12** ■ Distribution of the branches of the external carotid artery (shown in *dark red* ). AP, ascending palatine artery; F, facial artery; L, lingual artery; OC, occipital artery; PA, posterior auricular artery.

**FIG. 16.13** ■ Structures passing between the internal and external carotid arteries.

**FIG. 16.14** ■ Great blood vessels at the root of the neck.

**FIG. 16.15** ■ Relations of the subclavian vein.

**FIG. 16.16** ■ Beginning and termination of the internal jugular veins along with their tributaries.

**FIG. 16.17** ■ Deep (posterior) relations of the internal jugular vein.

**FIG. 16.18** ■ Superficial (anterolateral) relations of the internal jugular vein.

**FIG. 16.19** ■ Carotid arteries and nerves associated with them in the neck.

**FIG. 16.20** ■ Styloid apparatus.

**FIG. 16.21** ■ Lymph nodes of the head and neck.

**FIG. 16.22** ■ General plan of location of the lymph node groups in the region of the head and neck.

**FIG. 16.23** ■ Retropharyngeal lymph nodes.

**FIG. 16.24** ■ Waldeyer's internal and external rings.

**FIG. 17.1** ■ Features of the external nose. (A ) Front view. (B ) Lateral view.

**FIG. 17.2** ■ Osseocartilaginous framework of the external nose. (A ) Anterior view. (B ) Lateral view. (C ) Basal view.

**FIG. 17.3** ■ Interior of the nose. (A ) Division of the internal nose into right and left nasal cavities. (B ) Communication of nasal cavity to exterior through nostril and to nasopharynx through choana.

**FIG. 17.4** ■ Lining of the nasal cavity.

**FIG. 17.5** ■ Formation of the nasal septum.

**FIG. 17.6** ■ Arterial supply of the nasal septum.

**FIG. 17.7** ■ Nerve supply of the nasal septum.

**FIG. 17.8** ■ Formation of the lateral wall of the nasal cavity. Note the bones reducing the size of large maxillary hiatus of disarticulated skull. *Red circle* indicates the position of maxillary air sinus in disarticulated skull.

**FIG. 17.9** ■ Features of the lateral wall of the nasal cavity.

**FIG. 17.10** ■ Lateral wall of the nose with conchae removed showing openings of various air sinuses and nasolacrimal duct.

**FIG. 17.11** ■ Arterial supply of the lateral wall.

**FIG. 17.12** ■ Nerve supply of the lateral wall of the nose.

**FIG. 17.13** ■ Posterior rhinoscopy. (A ) Showing placement of mirror in the nasopharynx. (B ) Structures seen in the mirror.

**FIG. 17.14** ■ Positions of paranasal air sinuses on the surface. (A ) Front view. (B ) Side view.

**FIG. 17.15** ■ Schematic diagram to show the location of various paranasal sinuses in relation to the orbit.

**FIG. 17.16** ■ Coronal CT scan showing ethmoidal and maxillary air sinuses.

**FIG. 17.17** ■ Relations of maxillary sinus.

**FIG. 17.18** ■ Antral puncture (antroscopy).

**FIG. 18.1** ■ The ear and its subdivisions (external, middle, and internal ear).

**FIG. 18.2** ■ Auricle. (A) Features on the lateral surface of the auricle. (B) Crumpled elastic cartilage of the auricle.

**FIG. 18.3** ■ Sensory supply of the auricle: (A) lateral surface and (B) medial surface.

**FIG. 18.4** ■ Layers of the tympanic membrane.

**FIG. 18.5** ■ Tympanic membrane (schematic diagram). (A) External surface of tympanic membrane as seen through otoscope: 1, posterosuperior quadrant; 2, anterosuperior quadrant; 3, posteroinferior quadrant; 4, anteroinferior quadrant. (B) Medial surface of tympanic membrane showing

the course of the chorda tympanic nerve.

**FIG. 18.6** ■ Otoloscopic view of the tympanic membrane.

**FIG. 18.7** ■ Section through long axis of the petromastoid bone showing pharyngotympanic tube, middle ear (tympanic cavity), and mastoid antrum. Figure in the inset on the right side shows pistol.

**FIG. 18.8** ■ The shape and dimensions of the middle ear cavity.

**FIG. 18.9** ■ Subdivisions of the middle ear.

**FIG. 18.10** ■ Schematic diagram to show the boundaries (and their relations) of the middle ear. The middle ear is likened to a six-sided box and its lateral side is opened out. O, oval window; P, pyramid; PC, processus cochleariformis; PM, promontory; R, round window; S, sinus tympani; TP, tympanic plexus.

**FIG. 18.11** ■ Ear ossicles.

**FIG. 18.12** ■ Pharyngotympanic tube.

**FIG. 18.13** ■ Membranous labyrinth. (A) Schematic diagram to show separate four parts of labyrinth. (B) Complete labyrinth.

**FIG. 18.14** ■ Sensory receptors in different parts of the membranous labyrinth and nerves, which carry sensations from them.

**FIG. 18.15** ■ Cross-section of the cochlear canal showing boundaries of the cochlear duct and organ of Corti within it.

**FIG. 18.16** ■ Parts of the bony labyrinth.

**FIG. 18.17** ■ Diagrammatic representation of the cochlear duct within cochlear canal. Note that cochlear duct is filled with endolymph and scala vestibuli and scala tympani are filled with perilymph. CSF, cerebrospinal fluid.

**FIG. 18.18** ■ Schematic interior of the bony labyrinth showing features in the medial, posterior, and anterior walls of the vestibule.

**FIG. 18.19** ■ Direction of semicircular canals.

**FIG. 19.1** ■ Diagrammatic horizontal section through orbits showing: angle formed between lateral walls, distance between medial walls and their direction (parallel to each other), visual and orbital axes.

**FIG. 19.2** ■ Orbit. (A) Margins and walls. (B) Schematic diagram to show the bones forming the walls of the orbit. P= Palatine bone, M= maxilla.

**FIG. 19.3** ■ Presenting features in the four boundary walls of the orbit.

**FIG. 19.4** ■ Periorbita on roof of orbit.

**FIG. 19.5** ■ Sagittal section of the orbital cavity showing some of its contents.

**FIG. 19.6** ■ Extraocular muscles. (A) Origin of voluntary extraocular

muscle. The figure in the inset on the right side summarizes the origin of LPS, levator palpebrae superioris; SO, superior oblique; SR, superior rectus; IR, inferior rectus; MR, medial rectus; LR, lateral rectus; T, tubercle of Zinn. **(B)** Insertion of the recti muscles. **(C)** Insertion of the oblique muscles.

**FIG. 19.7** ■ Nerve supply of the extraocular muscles. NC, nasociliary nerve.

**FIG. 19.8** ■ Schematic diagram (modified after Starling) showing actions of various extraocular muscles of eyeball. IO, inferior oblique; IR, inferior rectus; LR, lateral rectus; MR, medial rectus; SR, superior rectus; SO, superior oblique.

**FIG. 19.9** ■ Fascia bulbi (Tenon's capsule).

**FIG. 19.10** ■ Suspensory and check ligaments of the eye. IO, Inferior oblique; IR, inferior rectus; LR, lateral rectus; MR, medial rectus.

**FIG. 19.11** ■ Course and distribution of two divisions of the oculomotor nerves in the orbit. **(A)** Superior division. **(B)** Inferior division.

**FIG. 19.12** ■ Course and distribution of the trochlear nerve in the orbit and also note the course of frontal and lacrimal nerves.

**FIG. 19.13** ■ Course and distribution of the abducent nerve in the orbit and also note the course and branches of the nasociliary nerve. V= superior ophthalmic vein, A= ophthalmic artery, N= nasociliary nerve.

**FIG. 19.14** ■ Branches and distribution of the ophthalmic nerve.

**FIG. 19.15** ■ Roots and distribution of the ciliary ganglion. CN3= Third cranial nerve, CN5= fifth cranial nerve, TG= trigeminal ganglion.

**FIG. 19.16** ■ Infraorbital and zygomatic nerves.

**FIG. 19.17** ■ Ophthalmic artery.

**FIG. 19.18** ■ Ophthalmic veins.

**FIG. 19.19** ■ Horizontal section of the eyeball showing its internal structure including three coats and visual axis.

**FIG. 19.20** ■ Meridional section of the eyeball showing ciliary region and the iridocorneal angle.

**FIG. 19.21** ■ Layers of the cornea.

**FIG. 19.22** ■ Ten layers of the retina.

**FIG. 19.23** ■ Stages in the development of the retina.

**FIG. 19.24** ■ Features in the fundus of eye as seen during ophthalmoscopy. **(A)** Actual photograph. **(B)** Schematic diagram of fundus.

**FIG. 19.25** ■ Arterial supply of the eyeball.

**FIG. 19.26** ■ Compartments of the eyeball.

**FIG. 20.1** ■ Schematic transection of the vertebral canal showing its contents.

**FIG. 20.2 ■** Vertebral venous plexus.

**FIG. 20.3 ■** Schematic transverse section of the spinal cord showing meninges and formation of meningeal sheaths onto the spinal nerve roots.

**FIG. 20.4 ■** Posterior view of part of the spinal cord showing ligamenta denticulata.

**FIG. 20.5 ■** Lumbar puncture. Insertion of needle in the interspinous space between L3 and L4.

**FIG. 20.6 ■** TS of spinal cord showing external features. PLS= Posterolateral sulcus, ALS= anterolateral sulcus.

**FIG. 20.7 ■** Spinal cord and spinal nerves.

**FIG. 20.8 ■** Cross-sections of the spinal cord in the cervical, thoracic, and lumbar regions. The shape of sections is given on the left side, whereas the shape of anterior and posterior horns is given on the right side.

**FIG. 20.9 ■** Transverse section of the spinal cord at mid-cervical level showing mainly descending (on left side) and ascending (on right side) tracts.

**FIG. 20.10 ■** Pyramidal tracts (corticospinal tract is shown in *red* and corticobulbar in *blue* ).

**FIG. 20.11 ■** Lateral and anterior spinothalamic tracts.

**FIG. 20.12 ■** Fasciculus gracilis and fasciculus cuneatus (posterior column-medial lemniscus pathway).

**FIG. 20.13 ■** Schematic diagram showing the posterior (*red*) and anterior (*blue*) spinocerebellar tracts.

**FIG. 21.1 ■** Parasagittal section of skull showing anterior, middle, and posterior cranial fossae. The inset shows the levels of anterior, middle, and posterior cranial fossae akin to three terraces with descending levels.

**FIG. 21.2 ■** Internal surface of the vault of the skull (calvaria).

**FIG. 21.3 ■** Diploic veins displayed by the removal of the outer table of the vault of the skull.

**FIG. 21.4 ■** Floor of the cranial cavity (the internal surface of the base of the skull). DS, dorsum sellae. ACF= anterior cranial fossa; MCF= middle cranial fossa; PCF= posterior cranial fossa. Figure in the inset on the right shows three descending steps akin to levels of floor of three cranial fossae.

**FIG. 21.5 ■** The four foramina in the greater wing of the sphenoid are present along a crescentic line, in its medial part.

**FIG. 21.6 ■** Structures passing through the superior orbital fissure.

**FIG. 21.7 ■** Structures passing through the foramen lacerum.

**FIG. 21.8 ■** Structures passing through the jugular foramen.

**FIG. 21.9 ■** Structures passing through the foramen magnum.

**FIG. 21.10 ■** Cranial and spinal dura.

**FIG. 21.11 ■** Coronal section through the posterior cranial fossa showing dural folds and dural venous sinuses enclosed in them. (A) Section through the anterior part. (B) Section through the middle part. (C) Section through the posterior part.

**FIG. 21.12 ■** Dural folds and dural venous sinuses enclosed within them, viewed from superolateral aspect.

**FIG. 21.13 ■** Tentorium cerebelli as seen from above.

**FIG. 21.14 ■** Formation of trigeminal cave. (A) Before invagination of the meningeal layer of the dura mater. (B) After invagination of the meningeal layer of the dura mater to form Meckel's cave (cavum trigeminale).

**FIG. 21.15 ■** Intracranial dural venous sinuses and their connections (lateral view).

**FIG. 21.16 ■** Cavernous sinuses as seen in the coronal section showing their relations and contents.

**FIG. 21.17 ■** Tributaries and communications of cavernous sinus (superior view). A, anterior intercavernous sinus; P, posterior intercavernous sinus; E, emissary vein.

**FIG. 21.18 ■** Schematic coronal section through the superior sagittal sinus showing arachnoid granulations and absorption of the cerebrospinal fluid.

**FIG. 21.19 ■** Location of hypophysis cerebri (pituitary gland).

**FIG. 21.20 ■** Parts of hypophysis cerebri as seen in sagittal section.

**FIG. 21.21 ■** Blood supply of pituitary gland. Note the hypothalamo-hypophyseal connections.

**FIG. 21.22 ■** Microscopic structure of pituitary gland.

**FIG. 21.23 ■** Bitemporal hemianopia (tunnel vision). T, temporal field of vision; N, nasal field of vision.

**FIG. 22.1 ■** Olfactory nerve and location of olfactory epithelium in the nasal cavity.

**FIG. 22.2 ■** Basic components of the visual pathway. EW, Edinger–Westphal nucleus.

**FIG. 22.3 ■** Oculomotor nerve. (A) The functional components and nuclei of the oculomotor nerve; (B) the distribution of the constitutional fibres of the oculomotor nerve.

**FIG. 22.4 ■** Origin, course, and distribution of the oculomotor nerve.

**FIG. 22.5 ■** Origin, course, and distribution of the trochlear nerve.

**FIG. 22.6 ■** Origin, course, and distribution of the abducent nerve.

**FIG. 22.7 ■** Different types of strabismus/squint caused by the lesions of

left 3rd (A), 4th (B) and 6th (C) cranial nerves, respectively.

**FIG. 22.8 ■** Trigeminal nerve. A. Functional components of the trigeminal nerve. B. Roots and divisions of the trigeminal nerve, TG = trigeminal ganglion.

**FIG. 22.9 ■** Trigeminal nerve. (A) Divisions and branches; (B) cutaneous distribution. AE, anterior ethmoidal; IT, infratrochlear; PE, posterior ethmoidal; SO, supraorbital; ST, supratrochlear; V1, ophthalmic division; V2, maxillary division; V3, mandibular division; 1, ciliary ganglion; 2, pterygopalatine ganglion; 3, otic ganglion; 4, submandibular ganglion. Z, Zygomatic branch.

**FIG. 22.10 ■** Functional components and nuclei of the facial nerve.

**FIG. 22.11 ■** Origin, course, and distribution of the facial nerve. SP, sympathetic plexus around internal carotid artery. (A,B,C,D – Various levels of infranuclear lesions of facial nerve – See Clinical Correlation)

**FIG. 22.12 ■** Effects of supranuclear (UMN) and infranuclear (LMN) lesions of the facial nerve.

**FIG. 22.13 ■** Schematic diagram showing the course and distribution of the vestibular and cochlear nerves. (A) Vestibular nerve; (B) cochlear nerve.

**FIG. 22.14 ■** Relationship of the last four cranial nerves at the base of the skull.

**FIG. 22.15 ■** Functional components and nuclei of the glossopharyngeal nerve.

**FIG. 22.16 ■** Course and distribution of the glossopharyngeal nerve.

**FIG. 22.17 ■** Functional components and nuclei of the vagus nerve.

**FIG. 22.18 ■** Course and distribution of the vagus nerve (right) in the head and neck.

**FIG. 22.19 ■** Functional components and nuclei of the accessory nerve.

**FIG. 22.20 ■** Distribution of the cranial and spinal roots of the accessory nerve.

**FIG. 22.21 ■** Functional components and nucleus of the origin of the hypoglossal nerve.

**FIG. 22.22 ■** Course and distribution of the hypoglossal nerve.

**FIG. 23.1 ■** Parts of the central nervous system.

**FIG. 23.2 ■** Left lateral aspect of the brain. Note the four lobes on the superolateral surface of the cerebral hemisphere.

**FIG. 23.3 ■** Median sagittal section of the brain.

**FIG. 23.4 ■** Interior aspect of the brain. Note the attachment of cranial nerves.

# SECTION I: Head and Neck

## OUTLINE

---

1. Introduction and overview of living anatomy of the head and neck
2. Osteology of the head and neck
3. Scalp, temple and face
4. Skin, superficial fascia and deep fascia of the neck
5. Side of the neck, sternocleidomastoid muscle and posterior triangle
6. Anterior region of the neck: Anterior triangle, ansa cervicalis and infrahyoid/strap muscles
7. Back of the neck, suboccipital region, cervical spinal column and joints of neck
8. Parotid region: Parotid gland and extracranial course of facial nerve
9. Submandibular region
10. Temporal fossa, infratemporal fossa, temporomandibular joint and pterygopalatine fossa
11. Thyroid and parathyroid glands, trachea and oesophagus
12. Pre- and paravertebral regions and root of the neck
13. Oral cavity, teeth and tongue
14. Pharynx and palate
15. Larynx

16. Blood supply and lymphatic drainage of the head and neck
17. Nose and paranasal air sinuses
18. Ear: External ear, middle ear, pharyngotympanic tube and internal ear
19. Orbit and eyeball
20. Vertebral canal and spinal cord
21. Cranial cavity, cranial meninges and pituitary gland
22. Cranial nerves

---

# Chapter 1: Introduction and overview of living anatomy of the head and neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Define head and neck region and discuss its clinical and functional significance.
- Enumerate the regions of head and discuss the important features of each region.
- Enumerate the regions of neck and discuss the important features of each region.

## Head

The head is the globular cranial end of the body, which connects to the body by a cylindrical neck. It contains **brain and special sense organs**, *namely, eyes for vision, ears for hearing and equilibrium, nose for smell, and tongue for taste*. It also provides openings for the respiratory and digestive systems.

Structurally and developmentally, the head is divided into two parts: cranium and face.

## Comparative anatomy

The cranium (also known as *braincase*) contains the brain. The face possesses openings of eyes, nose, and mouth.

A little description of comparative anatomy makes the distinction between the size of cranium and face easier to understand.

The sense of smell is one of the oldest sensibilities. The pronograde canines

(e.G., Dog) are guided predominantly by smell for searching food and sex. The other senses, such as touch, hearing, and vision play accessory roles. Therefore, they have well-developed snout, and, their face is located in front of the cranium (**Fig. 1.1** ).

**FIG. 1.1** ■ Change in position of face in relation to cranium during evolution. The face is located in front of cranium in dog, below and in front of cranium in monkey, and below the anterior part of cranium in humans. Note that the size of jaws is inversely proportional to the size of cranium. C, cranium; F, face.

The arboreal mode of life of apes and monkeys favoured the higher

development of visual, acoustic, tactile, kinaesthetic, and motor functions with improvement in their intelligence. In these animals, usefulness of the nose was lost and sense of smell became an accessory sense. Consequently, in orthograde monkeys, it resulted in the loss of the projecting snout, and their face is located below and in front of the cranium.

The supremacy of humans in animal kingdom is because of their large well-developed brain, which provides them the unlimited power of thinking, reasoning, and judgement.

To accommodate large brain, the size of cranium has also increased proportionately. Consequently, in plantigrade humans, the forehead is prominent and the face is located below the anterior part of the cranium.

It is important to note that size of jaws is inversely proportional to the size of cranium. Thus, the pronograde canine has larger jaws; an orthograde monkey has smaller jaws; whereas plantigrade human has smallest jaws. The reduction in the size of jaws occurred because of change in eating habits of these animals. The jaws are smallest in humans because they prefer to eat soft-cooked food. The size of jaws is larger in canines because they use it for holding, breaking, biting, tearing, and chewing the food. With receding jaws, the mouth is proportionately reduced in size.

In humans, eyes are placed in more frontal plane to enable stereoscopic vision. To permit freedom of mobility to the tongue for a well-articulated speech in humans, the alveolar arches are broadened and the chin is pushed forward, making the mouth cavity roomier. The **prominent chin is a characteristic feature of human beings**. The distinctive external nose with prominent dorsum, tip, and alae is characteristic of a human, although it has nothing to do with the sense of smell. Probably it serves to protect the eyes from injuries. The brow ridges are markedly reduced in humans as compared to other primates because of their prominent forehead.

## Living anatomy of head

The living anatomy of head mainly deals with the examination of surface features by visualization (inspection) and palpation of the living individuals to get information about the deeper structures in the regions of head. It is of immense importance in clinical examination of the patients.

It begins with the division of the head into regions and examining surface landmarks in each region.

The students are advised to practice finding these landmarks in each region on themselves or on their colleagues to develop the skill of examination.

## Regions of the head

Clinically, the head is divided into the following regions: *frontal, parietal, occipital, temporal, auricular, parotid, orbital, nasal, zygomatic, buccal, oral, and mental* (Fig. 1.2 ).

**FIG. 1.2** ■ Regions of the head. The aesthetic regions of face are marked by yellow colour.

### Frontal region (forehead)

The frontal region of the head is an area superior to the eyebrows and below the hairline. Eyebrows are the raised arches of skin with short, thick hairs above the supraorbital margins. Just deep to eyebrow is the curved bony ridge or superciliary arch. It is more prominent in adult males. The smooth non-hairy elevated area between the eyebrows is called **glabella** , which tends to be flat in children and adult females, and forms a rounded prominence in adult males. It is important to note that the pineal gland (soul of body by Descartes) lies about 7 cm behind the glabella (soul of body by Descartes). It

is responsible for dark and light cycles of environment.

The prominence of forehead, the frontal eminence is evident on either side above the eyebrow. The frontal prominence is typically more pronounced in children and adult females.

### **Parietal region**

It is an area limited anteriorly by hairline and posteriorly by a coronal plane behind the parietal eminences and on either side by the temporal line. The parietal eminence can be felt on either side in this region about 5 cm above the auricle. The parietal prominences are evident on or just in front of the interauricular line.

### **Occipital region**

The occipital region is an area of cranium behind the parietal eminences and above the external occipital protuberance and superior nuchal lines.

The most prominent point in the occipital region is called **opisthocranium** or **occiput**. The external occipital protuberance can be felt in the median line just above the nuchal furrow. The superior nuchal line, one on either side of external occipital protuberance, runs laterally with its convexity facing upwards.

The soft tissue covering frontal, parietal, and occipital regions forms the **scalp**.

### **CLINICAL CORRELATION**

The large area of scalp over the vault of skull is thickly covered by terminal hair. Because of presence of hair, many lesions in this area remain unnoticed by both clinicians and patients. Hence, this area should be carefully examined by the clinicians.

### **Temporal region (temple)**

The temporal region is the area on the side of skull between the temporal line above and zygomatic arch below (Fig. 1.3). It is the site of attachment of temporalis muscle, which can be palpated when the teeth are clenched repeatedly. Try on yourself. Soft tissue in the temporal region includes skin, subcutaneous tissue, temporal fascia, and temporalis muscle. In the anterior part of temporal region, deep to soft tissues is a small area where four bones meet is called **pterion** (Fig. 1.3). This region is clinically important because extradural haematoma commonly occurs deep to it. Further it is the site of

entrance to cranial cavity in craniotomy to remove the extradural haematoma. Pterion is described in detail on page 19. The temporal region (temple) is described in detail on page 52.

**FIG. 1.3 ■** Surface landmarks on the lateral aspect of the head.

### **Auricular region**

The auricular region includes fleshy oval flap of the external ear (auricle) and external acoustic meatus.

The auricle collects the sound waves. The external auditory meatus is a tube through which sound waves are transmitted to the middle ear within the skull.

Observe the following surface features of the auricle (**Fig. 1.4**):

- The superior and posterior free margins of the auricle forming a kind of rim are called *helix*, which ends inferiorly at the fleshy protuberance of the ear called *ear lobule*.
- The upper end of the helix is typically at the level of the eyebrows and the glabella.

- The lobule is approximately at the level of the apex of the nose.
- The portion of the auricle anterior to the external auditory meatus is a small nodular flap of tissue called **tragus** . It projects posteriorly, partially covering and protecting the external auditory meatus. The condyle of mandible can be palpated by putting the tip of finger just in front of tragus and then opening and closing the mouth.
  - Another flap of tissue opposite the tragus is the antitragus.
- Between the **tragus** and **antitragus** is a deep notch called **intertragic notch** .
- A semicircular ridge anterior to the helix is called **antihelix** .
- The upper end of antihelix divides into two crura enclosing a triangular depression called **triangular fossa** . The depressed hollow of the auricle is called **concha** .
- The upper end of the helix which extends backwards to some extent into concha is called **crux of helix** .

**FIG. 1.4 ■** Lateral view of right auricle: ( **A** ) schematic diagram and ( **B** ) actual picture.

### CLINICAL CORRELATION

The external auditory meatus and tragus are important landmarks (for dental surgeons) to use when taking extraoral radiograph and administering local

anaesthesia on a patient.

The **pulsations of superficial temporal artery** can be felt by putting the fingertip just in front and above the tragus on the root of zygoma.

## Parotid region

As the name implies, it is the region around the ear (para = adjacent to; otic = ear). It is limited in front by anterior border of masseter, behind by mastoid process, and below by line extending from angle of mandible to the tip of mastoid process. This region is occupied by the *parotid gland*.

The *mastoid process* lies behind the lower part of the ear. Its anterior border, tip, and posterior border can be easily felt.

The *masseter* overlies the ramus of the mandible. It can be felt when the teeth are clenched.

## CLINICAL CORRELATION

The parotid gland is often enlarged in mumps, following its infection by mumps virus. This produces a painful swelling in the parotid region elevating the ear lobule.

The parotid gland is also the site of slow-growing painless tumour called *mixed parotid tumour*.

## Orbital (ocular) region

The ocular region includes the eyeball and associated structures. Most of the surface features of the ocular region protect the eye ([Fig. 1.5](#)).

**FIG. 1.5 ■** Frontal view of the left eye.

Eyebrow is a ridge of hair along the superciliary arch above the orbit, which protects the eyes against sunlight and mechanical blow. The two movable *eyelids* reflexly close to protect eyes from foreign particles and bright sunlight (for details on eyelids, see [Chapter 3](#)). The *eyelashes* are a row of hairs at the margins of eyelids. The eyelashes prevent air-borne objects from contacting the eyeball.

Behind the lateral part of the upper eyelid and within the orbit is the **lacrimal gland**, which produces lacrimal fluid or tears. The tears wash away chemical and foreign particles and lubricate the front of the eye to prevent the surface of the eyeball, particularly the all-important *cornea* from drying.

The *conjunctiva* is a delicate thin mucous membrane which lines the inner surface of the eyelids and the front of the sclera of the eyeball. It aids in reducing friction during blinking.

The *sclera*, the 'white' of the eye is seen on either side of cornea.

The *cornea* is the circular transparent anterior portion of the eyeball.

The outer corner where the upper and lower eyelids meet is called *lateral (outer) canthus*. The inner corner where the two eyelids meet is called *medial canthus*. A fleshy pinkish elevation in the medial angle of the eye is called *lacrimal caruncle*.

Palpate the following landmarks in this region ([Fig. 1.6](#)) yourself:

- Supraorbital notch on the highest point of supraorbital margin about

2.5 cm from the midline.

- Frontozygomatic suture, which is marked by a slight irregular depression on the lateral orbital margin.

**FIG. 1.6** ■ Surface landmarks on frontal aspect of the head.

## CLINICAL CORRELATION

The condition of the eyes profoundly affects the facial appearance. **Lesions affecting the eye and its associated structures** are enormous. A few easily recognizable and surgically relevant conditions are as follows:

- *Arcus senilis*, a white rim around the outer edge of the iris, is commonly seen in elderly people. It occurs because of sclerosis and deposition of cholesterol in the edge of the cornea.
- *Xanthelasma* are fatty plaques in the skin of the eyelids. They look like masses of yellow opaque fat. If multiple and growing, they indicate underlying abnormality of cholesterol metabolism, diabetes, or arterial disease.
- *Exophthalmos* is a forward protrusion of the eyeball from its normal

position in the orbit. The commonest cause of both bilateral and unilateral exophthalmos is thyrotoxicosis (hyperthyroidism).

- *Ectropion* is the eversion of the lower eyelid.

## Nasal region

The main feature of nasal region is the external nose. It is a pyramidal projection in the middle third of the face with its root up and base downwards (Fig. 1.6). The *root* of the nose is located between the eyes inferior to glabella. The firm narrow bony portion below the nasion is the bridge of the nose. The nose below this level has pliable cartilaginous framework that maintains the openings of the nose. The tip of the nose is called *apex*. It is flexible when palpated because it is made up of cartilage. Inferolateral to the apex on either side is a *nostril* (or naris). The nostrils are separated from each other by a midline nasal septum. The nares are bounded laterally by wing-like *alae of the nose*. The alae of nose form the flared outer margin of each nostril.

The distinctive external nose with exuberant growth of cartilages forming prominent dorsum, tip, and alae is a characteristic feature of human beings.

A well-marked depression at the root of the nose is called *nasion*.

## CLINICAL CORRELATION

- **Saddle nose:** A nose whose bridge is depressed and widened.
- **Rhinophyma:** The nasal skin covering the alar cartilages is thick and adherent, and contains many sebaceous glands. The hypertrophy and adenomatous changes of these glands give rise to a lobulated tumour called rhinophyma.

## Infraorbital region

The infraorbital region of head is located below the orbital region and corresponds to the upper part of the anterior surface of the maxilla. The **infraorbital foramen** is located in this region about 1 cm below the infraorbital margin in line with the supraorbital notch or foramen (Fig. 1.6). The knowledge of its location is important for giving **infraorbital nerve block**.

## Zygomatic region

The zygomatic region overlies the zygomatic (cheek) bone and zygomatic

arch.

The zygomatic arch extends from just inferior to lateral margin of the eye towards the upper portion of the auricle. Inferior to the zygomatic arch and just anterior to the tragus of the ear is the **temporomandibular joint**. The zygomatic arch is bony bridge that spans the interval between the ear and the eye. The zygomatic bone forms the bony prominence of the cheek below and lateral to the orbit.

The movements of the temporomandibular joint can be felt by opening and closing the mouth or moving the lower jaw from side to side. One way to feel the movements of head of mandible is to gently place a finger in front of tragus and ask the patient to open and close the mouth.

### **Buccal region**

The buccal region of face is a broad area of the face between the nose, mouth, and parotid region. It overlies the buccinator muscle. It is made of soft tissues of the cheek.

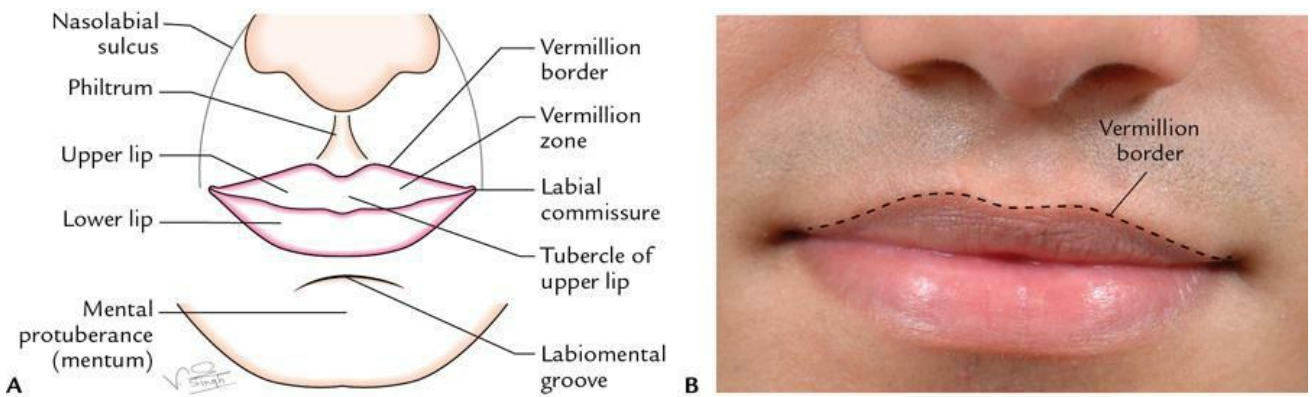

The **pulsations of facial artery** can be felt about 1.25 cm lateral to the angle of the mouth.

### **Oral region**

The structures of the oral region include fleshy upper and lower lips, and the structures of oral cavity that can be observed when the mouth is widely open.

The lips are chiefly composed of muscles covered externally by skin and internally by mucous membrane. Each lip has a pinkish zone between skin and mucous membrane called *vermillion zone*. The lips are outlined from the surrounding skin by a rim of paler skin called *vermillion border*. The contour of line formed by the vermillion border of upper lip forms a shape of *cupid bow*. The small triangular median depression in the upper lip is called *philtrum*. The apex of philtrum is towards the nasal septum and the base downwards where it terminates in a thicker area called *tubercle of the upper lip*.

The corners of mouth where upper and lower lips meet are called *labial commissure*. The groove running upward between the labial commissure and the alae of nose is called *nasolabial sulcus*. The lower lip is separated from the chin by a horizontal groove called *labiomenthal groove* (Fig. 1.7).

**FIG. 1.7** ■ Frontal view of the lips: ( **A** ) schematic diagram and ( **B** ) actual picture.

## CLINICAL CORRELATION

- The colour of the lips and the mucous membrane of the oral cavity are clinically important; lips may appear pale in patients with severe *anaemia* or bluish in people suffering from lack of oxygenation of blood (*cyanosis*). A lemon yellow tint of lips may indicate *jaundice*.
- The lips are a common site for carcinoma, mostly affecting individuals older than 60 years. Carcinoma of the lip usually occurs in lower lip (93%) as compared to the upper lip (5%).

The bone underlying the upper lip is the alveolar process of the maxilla, whereas the bone underlying the lower lip is the alveolar process of the mandible. The alveolar processes maxilla and mandible contain teeth and are called maxillary and mandibular teeth respectively.

### **Mental region**

The mental region is an area of face below the lower lip and is characterized by presence of mental protuberance or *mentum*, a privileged feature of human beings (Fig. 1.7).

Important bony landmarks in the region of the head are summarized in Table 1.1.

### **N. B.**

For rejuvenation of face, the knowledge of its aesthetic regions/aesthetic units is very very important, particularly to cosmetic surgeons.

The aesthetic regions of face includes (Fig. 1.2):

- Frontal region
- Orbital regions
- Zygomatic regions
- Nasal region
- Infraorbital regions
- Oral region
- Mental region
- Buccal regions
- Parotid regions
- Auricular regions
- Temporal regions.

 **TABLE 1.1**

### Bony landmarks in the region of head

Landmark	Location
<b><i>Mental protuberance/mentum</i></b>	Protuberance of the chin
<b><i>Nasion</i></b>	Depression at the root of nose at the junction of frontonasal and internasal sutures
<b><i>Glabella</i></b>	Smooth nonhairy area between the eyebrows above nasion
<b><i>Vertex</i></b>	Highest point on the top of head in the midline
<b><i>External occipital protuberance</i></b>	Knob-like bony projection at the upper end of nuchal furrow
<b><i>Inion</i></b>	Apex of external occipital protuberance
<b><i>Gonion</i></b>	Angle of mandible
<b><i>Head of mandible</i></b>	In front of lower part of the tragus
<b><i>Preauricular point</i></b>	In front of upper part of the tragus
<b><i>Mastoid</i></b>	Behind the lower part of the auricle

<b><i>Præcortex</i></b>	4 cm above the midpoint of zygomatic arch and 3.5 cm behind and above the frontozygomatic suture
<b><i>Asterion</i></b>	Depression – 2.5 cm behind the upper part of the root of ear
<b><i>Supraorbital notch/foramen</i></b>	On the supraorbital margin 2.5 cm from midline
<b><i>Infraorbital foramen</i></b>	1 cm below infraorbital margin and 1.25 cm lateral to the side of nose
<b><i>Mental foramen</i></b>	2.5 cm lateral to symphysis menti and 1.25 cm above the lower border of mandible
<b><i>Frontal prominence</i></b>	Area of maximum convexity on either side of forehead where top, front, and side of head meet
<b><i>Parietal prominence</i></b>	Area of maximum convexity on either side in the parietal region where back, top, and side of head meet (area of maximum transverse diameter of the skull)

## Examination of oral cavity

Examine following structures of oral cavity by asking your friend to open his or her mouth widely ([Fig. 1.8](#)):

- The part of oral cavity inside the alveolar arches is called *oral cavity proper*. It contains a mobile muscular organ, the **tongue**.
- The oral cavity is lined by a mucous membrane or mucosa. The inner aspects of the lips are lined by pink and thick *labial mucosa*. The labial mucosa is continuous with the equally pink and thick *buccal mucosa* that lines the inner cheek.
- The space between cheek/lip and gum is called *vestibule*.
- On the inner aspect of buccal mucosa opposite the upper second molar tooth is a small elevation called *parotid papilla* on which opens the parotid duct.
- The *gingiva* is a part of oral mucosa that covers the alveolar processes of the jaws.
- The *roof of oral cavity* which presents two portions: a firm anterior portion is called *hard palate* and a flexible posterior portion is called *soft palate*.
  - A cone-shaped projection hanging down from the middle of the posterior free margin is called *uvula of the palate*, which is

- continuous with palatopharyngeal arch on each side.
- A dense pad of soft tissue behind the last molar tooth is called *retromolar pad*.
  - The *floor of mouth* is located inferior to the ventral surface of the tongue.

**FIG. 1.8** ■ Features of the oral cavity and oropharynx.

**N.B.**

The oral cavity provides entrance into the throat or the pharynx.

In addition to above, one can easily examine following features in the oropharynx (**Fig. 1.8**):

1. A curved, leaf-like flap of cartilage is located behind the base of tongue and in front of oropharynx. It is *epiglottis*, the cartilage of the larynx.
2. Mass of lymphoid tissue projecting on either side into the lateral wall of the oropharynx is called *palatine tonsil* (Fig. 1.8 ). The palatine tonsils are generally called *tonsils* by the patients. The tonsil lies in triangular fossa called tonsillar fossa located between the palatoglossal and palatopharyngeal arches. Note that the tonsils lie opposite the angle of mandible between the back of tongue and soft palate.

## Neck

The neck is approximately a cylindrical region of the body that connects the head to the trunk. It supports and permits the movements of the head.

The cervical spine in the posterior part of neck contains cervical part of spinal cord. The anterior part of neck contains parts of respiratory and digestive systems and thyroid and parathyroid glands. On either side, the neck contains major blood vessels and vagus nerve.

### N.B.

A newborn baby has no visible neck because its lower jaw and chin touch the shoulders and thorax.

## Topographical organization of the neck

The neck is flexible and provides passage to several structures such as spinal cord, trachea, oesophagus, blood vessels supplying the brain, and the last four cranial nerves. All these structures are essential for the sustenance of life.

The **investing layer of deep cervical fascia** encloses the neck like a collar. It splits to enclose sternocleidomastoid and trapezius muscles in its course around the neck. The two fascial layers (called *pretracheal* and *prevertebral fasciae* ) extending from the investing layer of deep fascia across the structures within the neck divide the neck into anterior and posterior compartments (Fig. 1.9 ).

**A**

**B**

**FIG. 1.9** ■ The basic plan of the neck in cross-section: ( **A** ) disposition of deep cervical fascia and delineation of compartments of neck ( **B** ) schematic diagram showing compartments of the neck.

On either side, between anterior and posterior compartments pass major neurovascular structures of the neck. They get surrounded by a tubular

sheath of deep fascia (carotid sheath) and form *lateral compartments of the neck* .

### Compartments of neck (Fig. 1.9 B)

Topographically, the structures of the neck are organized into four compartments, namely (1) anterior/visceral compartment, (2) posterior/vertebral compartment, and (3 and 4) right and left lateral/vascular compartments.

The details of these compartments are shown in [Figure 1.10](#) .

**FIG. 1.10** ■ Cross-section of the neck showing anatomical details of various compartments of neck. S, spinal cord; C, cervical vertebra.

### Anterior/visceral compartment

The basic topography of the anterior compartment is simple. In the midline, there are two tubes: the respiratory tube (larynx and trachea) in front and digestive tube (pharynx and oesophagus) behind.

The thyroid gland clasps the front and sides of the larynx and trachea, and overlaps the carotid tree on either side.

These structures are bounded anteriorly by pretracheal fascia, which extends on either side to merge with the investing layer of deep cervical fascia deep to sternocleidomastoid.

## Posterior/vertebral compartment

The posterior compartment of neck consists of cervical part of vertebral column and its surrounding musculature (Fig. 1.10 ). This musculoskeletal block is bounded by prevertebral fascia, which merges behind on either side with the deep fascia enclosing the trapezius muscle. The musculature includes: (1) prevertebral muscles located in front of the cervical column, (2) scalene muscles extending between the neck and upper two ribs, and (3) muscles of the back of the neck.

The vertebral canal within the cervical vertebral column provides passage to the **spinal cord** . The roots of cervical spinal nerves come out through intervertebral foramina in this region. The ventral rami of the first four cervical nerves form the *cervical plexus* and ventral rami of the lower four cervical nerves along with ventral ramus of T1 form the brachial plexus.

The neck, therefore, is a complex region of the body. The spinal cord, digestive and respiratory tracts, and major blood vessels traverse this highly flexible area. The neural structures present in the region include last four cranial nerves and cervical and brachial plexuses. Several organs are also located here. The musculature of neck produces an array of movements in this area. The layout of these structures is depicted in Figure 1.11 to understand the topography of the neck.

**FIG. 1.11 ■ Basic layout of structure of the neck.**

### **Lateral or vascular compartment (Figs 1.9 B and 1.10 )**

On either side of the midline tubes, the neck contains major blood vessels and vagus nerve. In fact there are several ascending and descending neurovascular structures, such as carotid tree consisting of common carotid, internal carotid and external carotid arteries, internal jugular vein, and last four cranial nerves. At the upper end, these structures enter or leave the skull through various foramina in the base of the skull, namely, foramen ovale, foramen spinosum, carotid canal, and jugular foramen.

### **Living anatomy of neck**

The living anatomy of neck mainly deals with examination of surface features by visualization (inspection), palpation, percussion and auscultation to get information of deeper structures. This will help students immensely during their clinical year while examining the patients.

### **Regions of the neck**

The neck is divided into four regions:

1. Anterior region
2. Right lateral region
3. Left lateral region
4. Posterior region (nuchal region).

### **Anterior region (cervix)**

Anterior region of the neck contains strap muscles, digestive (pharynx and oesophagus) and respiratory (larynx and trachea) tracts, vessels to and from the head, last four cranial nerves, and thyroid and parathyroid glands.

The following structures can be easily palpated in the anterior region of the neck.

#### **In the midline (Fig. 1.12 ):**

1. **Hyoid bone:** It is situated in a depression behind and slightly below the chin and can be easily felt if the neck is slightly extended. The hyoid bone can be gripped between the thumb and index finger and moved from side to side.
2. **Thyroid cartilage:** It is the most prominent feature in the anterior region of the neck, particularly anterior angle formed by fusion of its two laminae which form the laryngeal prominence. It is prominent in males and called *Adam's apple*, whereas in females, it is not usually apparent. The thyroid notch, the curved upper border of the thyroid cartilage can be easily palpated.
3. **Cricoid cartilage:** It can be easily palpated below the thyroid cartilage.
4. **Tracheal rings:** These can be palpated below the cricoid cartilage by pressing gently backwards above the jugular notch.
5. **Isthmus of thyroid gland:** It lies on the front of the 2nd, 3rd, and 4th tracheal rings and can be palpated.
6. **Suprasternal (jugular) notch:** It is a depression just superior to sternum between the medial expanded ends of the clavicle and can be easily palpated.

**FIG. 1.12** ■ Surface landmarks in anterior median and lateral regions of the neck.

Vertebral levels of some of the structures that can be palpated in the anterior midline of the neck are given in [Table 1.2](#) .

**On either side of the midline** ([Fig. 1.12](#) ):

1. **Thyroid lobe:** It can be palpated on either side just below the level of cricoid cartilage.
2. **Common carotid artery:** It can be observed and palpated on either side at the level of junction between the larynx and trachea along the anterior border of sternocleidomastoid muscle.

**TABLE 1.2**

### Vertebral levels of structures in anterior midline of the neck

Structure	Vertebral level
Hyoid bone	C3
Upper border and notch of thyroid cartilage	C3/C4
Thyroid cartilage	C4–C5
Cricoid cartilage	C6

Suprasternal notch	T2/T3
--------------------	-------

The common carotid artery can be compressed against the prominent anterior tubercle of transverse process of the 6th cervical vertebra called *carotid tubercle* (*Chassaignac's tubercle* ).

### Right and left lateral regions (right and left sides of the neck)

The lateral regions on either side are composed of two large superficial muscles of the neck and cervical lymph nodes.

The following structures can be palpated in the lateral region:

1. **Mastoid process:** It can be easily felt behind the lower part of the auricle.
2. **Clavicle:** It is easily visible in thin people and palpable along its entire extent except in morbidly obese persons because it is subcutaneous throughout.
3. **Sternocleidomastoid:** It can be palpated along its entire length. When the head is turned to the opposite side it forms a prominent raised ridge that extends diagonally from mastoid process to sternum. The tendon of this muscle becomes especially prominent to the side of the jugular notch.
4. **Trapezius:** Anterior border of trapezius becomes prominent when the person is asked to shrug his or her shoulder against the resistance.
5. **External jugular vein:** It can be seen as it crosses obliquely across the sternocleidomastoid muscle, particularly if a person is angry or if the collar of his or her shirt is too tight.
6. **Transverse process of atlas vertebra:** It can be felt on deep pressure midway between the angle of the mandible and the mastoid process.

### CLINICAL CORRELATION

**Cervical lymphadenitis:** Cervical lymph nodes in the lateral region of the neck often become swollen and painful from infections of the oral and pharyngeal regions.

### Posterior region (or nuchal region)

Posterior region of neck includes cervical vertebral column, spinal cord, and associated muscles etc.

Following structures can be palpated in the posterior region of the neck

(Fig. 1.13 ):

1. **External occipital protuberance:** It can be easily palpated with inion at its summit at the upper end of nuchal furrow in the posterior midline of the neck.
2. **Superior nuchal line:** It can be sometimes palpated as a curved bony line with concavity below extending from external occipital protuberance to the mastoid process.
3. **Spine of 7th cervical vertebra (vertebra prominens):** It can be felt at the lower end of nuchal furrow, especially when the neck is flexed.
4. **Ligamentum nuchae:** It is raised when the neck is flexed and extends from spine of C7 vertebra below to the external occipital protuberance above.

**FIG. 1.13** ■ Surface landmarks in posterior region of the neck.

## CLINICAL CORRELATION

Clinically, posterior region of neck is extremely important because of the debilitating damage viz. broken neck it sustains from *whiplash injury* .

### Triangles of the neck

The neck is conventionally divided into various triangles. The sternocleidomastoid muscle transects the side of neck obliquely on each side and divides it into anterior and posterior cervical triangles ([Fig. 1.14](#) ). The triangles of neck are described in detail in [Chapters 5](#) , [6](#) , and [7](#) .

**FIG. 1.14** ■ Location of anterior and posterior triangles of the side of neck.

## Golden Facts to Remember

• **Normal shape of head (Normocephaly)**

Egg-shaped, slightly wider posteriorly and narrower anteriorly

• <b>Most expressive feature of the face</b>	Eyes
• <b>Most projecting part of the face</b>	Nose
• <b>Most important surface landmark of head which can neither be seen nor palpated</b>	Pterion
• <b>Most important surface landmark in the region of neck</b>	Cricoid cartilage
• <b>Most prominent feature on the front of neck in the midline</b>	Laryngeal prominence/Adam's apple
• <b>Chief characterizing facial feature of humans</b>	Prominent nose

## CLINICAL CASE STUDY

A 20-year-old medical student went to a hill station on his motorbike to enjoy his summer vacation. After enjoying his holidays, while returning home, his bike hit a rock and overturned. He became unconscious. He was rescued and taken to a nearby hospital by some tourists. **The attending physician first assessed the level of his consciousness using Glasgow Coma Scale**. He regained consciousness by the time he was being examined in the hospital. He had superficial wounds in the temporal region of his head but had no other obvious injuries. Radiographs of his skull were taken, which did not reveal any fracture or haematoma. He was discharged from the hospital 1 h after being given first aid.

### Questions

- 1 Enumerate any four regions in cranial part of the head.
- 2 What is 'Glasgow Coma Scale'?
- 3 What are the boundaries of temporal region?

### Answers

1. (a) Frontal region, (b) parietal region, (c) temporal region, and (d) occipital region.
2. It is a clinical scale used to measure the level of consciousness after brain injury by testing certain functions and seeing their response. The baseline observation of this sort forms an important first step in the assessment of every case of head injury, and gives a good initial indication of the degree of brain damage.

## Glasgow Coma Scale (GCS)

Function tested	Response	Score
Eye opening response	Spontaneous	4
	To verbal command	3
	To pain	2
	No response	1
Best verbal response	Oriented and converses	5
	Disoriented and converses	4
	Inappropriate words	3
	Incomprehensible sounds	2
	No response	1
Best motor response	Obeys verbal commands	6
	Localizes pain	5
	Flexes normally	4
	Flexes abnormally	3
	Extends	2
	No response	1
Total score	Ranges from: 3 to 15	
<i>Conclusion</i> Best response: 15 Comatose patient: 8 or less Totally unresponsive: 3		

3. The temporal region is bounded above by temporal line and below by zygomatic arch.

---

# Chapter 2: Osteology of the head and neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Define skull and subdivide it into neurocranium and viscerocranium. Give a brief account of cranial and visceral skeleton.
- Describe the anatomical position of skull, identify and locate the individual bones in skull. **AN 26.1**
- Describe the features of norma frontalis, verticalis occipitalis, lateralis, and basalis. **AN 26.2**
- Describe cranial cavity, its subdivisions, its foramina and structures passing through them. **AN 26.3**
- What are the differences between male and female skulls?
- Write short notes on: (a) pterion, (b) fontanelles, (c) age changes in mandible (i.e., differential features of mandible in child, adult, and old age), and (d) styloid process.
- Describe the morphological features of mandible. **AN 26.4**
- Give the anatomical basis of: (a) extradural haematoma, (b) decreased salivation and loss of taste sensations in the anterior two-third of tongue, (c) fracture of mandible, and (d) interparietal bone.
- Enumerate: (a) muscles attached on ramus of mandible, (b) nerves closely related to mandible, and (c) structures attached to styloid process, and (d) parts of maxilla.
- Describe the features of typical and atypical cervical vertebrae. **AN 26.5**

The study of osteology (bony skeleton) of head and neck forms the basis to

understand this region. *The skeleton of head and neck consists of skull, cervical vertebrae, and hyoid bone.* The students should study the skull and cervical vertebrae thoroughly relating their main features to the bony points which can be felt in a living individual. The prominences and depressions on the bony surface are landmarks for attachments of the muscles, tendons, and ligaments. The openings in the bone are also landmarks where various nerves and blood vessels enter or exit.

## Bones of head AN 26.1

The bony skeleton of the head is termed **skull** (Fig. 2.1 ). It consists of 22 bones excluding ear ossicles. Except mandible (bone of lower jaw), all the bones of skull joined together by sutures, are immobile and form the **cranium** . However, the two terms skull and cranium are generally used synonymously.

**FIG. 2.1 ■** Skull: ( **A** ) anterior/frontal view and ( **B** ) lateral view. (Source: Fig. 8.18, page 855, *Gray's Anatomy for Students* , Richard L Drake, Wayne Vogl, Adam WM Mitchell. Copyright Elsevier Inc. 2005, All rights reserved.)

### Parts of the skull (Fig. 2.2 )

The skull is subdivided into two parts:

1. **Cranial skeleton:** An upper dome-shaped part which covers the cranial cavity containing brain is called *cranial vault /calvaria* . It is attached to the skull base below. The calvaria along with skull base is called **cranial skeleton/cranium** .
2. **Facial skeleton:** A lower anterior part is called *facial skeleton*, which

includes mandible.

**FIG. 2.2 ■** Skull showing cranial skeleton (*orange colour*) and facial skeleton (*violet colour*) . ( **A** ) Frontal view; ( **B** ) lateral view.

The cranium (cranial skeleton) is a strong and rigid container for the brain, whereas the facial skeleton is a rather fragile and light basis for face. The facial skeleton lies below the anterior part of the cranium in human beings.

Many anatomists use alternative terms, **neurocranium** for the cranial skeleton and **viscerocranium** for the facial skeleton.

The cranial cavity is described in detail in [Chapter 21](#) .

## Functions of the skull

The functions of the skull are as follows:

1. Provides case for protection of the brain and its coverings (meninges).
2. Provides cavities for accommodation of organs of special senses such as sight, hearing, equilibration, smell, and taste.
3. Provides openings for the passage of air and food.
4. Accommodates teeth and jaws for mastication.

## N.B.

The term cranium (Gk. *cranium* = skull) is sometimes used to mean the skull without mandible.

## Bones of the skull

The skull is made up of 22 bones, excluding ear ossicles.

1. **Cranial skeleton**, consisting of **eight bones** , out of which two are paired and four unpaired.

Paired bones	Unpaired bones
<ul style="list-style-type: none"><li>• Parietal</li><li>• Temporal</li></ul>	<ul style="list-style-type: none"><li>• Frontal</li><li>• Occipital</li><li>• Sphenoid</li><li>• Ethmoid</li></ul>

2. **Facial skeleton** , consisting of 14 bones, out of which 6 are paired and 2 unpaired:

Paired bones	Unpaired bones
<ul style="list-style-type: none"><li>• Maxilla</li><li>• Zygomatic</li><li>• Nasal</li></ul>	<ul style="list-style-type: none"><li>• Mandible</li><li>• Vomer</li></ul>

- |   |  |
|---|--|
| <ul style="list-style-type: none"> <li>• Lacrimal</li> <li>• Palatine</li> <li>• Inferior nasal concha</li> </ul> |  |
|---|--|

## **Joints of the skull**

The bones of the skull are mostly united at immovable joints called **sutures** . The connective tissue uniting the bones is called **sutural ligament** .

Exception to this rule are:

- *Synovial joints* , a mandible is connected to the cranium by synovial temporomandibular joints, which are freely movable joints.
- *Gomphoses* , slightly movable specialized fibrous joints between teeth and their sockets
- *Synchondrosis* , a primary cartilaginous joint between basisphenoid and basiocciput.

## **N. B.**

All the bones of the skull are immovable except for the mandible which permits free movements. The ear ossicles within the middle ear are also mobile, but conventionally they are not included in the skeleton of the head.

## **Anatomical position of the skull AN 26.1**

It is the position of skull ([Fig. 2.3](#) ) in which the orbital cavities are directed forwards, and lower margins (infraorbital margins) of the orbits and upper margins of external acoustic meatuses lie in the same horizontal plane (**Frankfurt's plane** ).

**FIG. 2.3 ■** Anatomical position of the skull.

### **N.B.**

A horizontal line formed by joining the infraorbital margin and the centre of external auditory meatus is called **Reid's baseline**.

## **Study of skull as a whole AN 26.2**

The study of skull as a whole is of greater importance to most health professionals than the study of unnecessary details of the individual bones.

The skull can be studied from outside or from inside (after removing the calvaria or skull cap).

### **Exterior of the skull**

The external features of the skull are studied from the following five different aspects:

1. Superior aspect (*norma verticalis*)
2. Posterior aspect (*norma occipitalis*)
3. Anterior aspect (*norma frontalis*)
4. Lateral aspect (*norma lateralis*)
5. Inferior aspect (*norma basalis*).

When the skull is viewed from superior aspect, it is called *norma verticalis*

; when from posterior view, *norma occipitalis* ; when from anterior aspect, *norma frontalis* ; when from lateral aspect, *norma lateralis* ; and when from inferior aspect, *norma basalis*.

### **Norma verticalis (Fig. 2.4 )**

When the skull is viewed from above, it appears oval, being wider posteriorly than anteriorly.

**FIG. 2.4 ■** Norma verticalis.

It presents the following features:

### **Bones and sutures**

The bones are frontal, parietal, and occipital. They are located as follows:

1. **Frontal bone** (squamous part) anteriorly.
2. **Parietal bones** (paired) on each side of midline.
3. **Occipital bone** (squamous part) posteriorly.

These bones are united by the following three sutures:

1. **Coronal suture** (L. = a crown), between frontal and two parietal bones. It crosses the cranial vault from side-to-side.
2. **Sagittal suture** (L. = an arrow), between two parietal bones. It lies in the median plane.
3. **Lambdoid suture**, between occipital and two parietal bones. It is shaped like the letter lambda, hence its name.

### N.B.

- The **metopic suture** is occasionally present in the median plane of the frontal bone in 3–8% cases.  
It represents the remnant of *metopic suture* between the two halves of the frontal bone in foetal skull. It is one of the first suture to close physiologically. It starts closing at the age of 3 months and get completely closed at the age of 8 months.
- Isolated **sutural bones (Wormian bones)**, ossified from separate centres are often seen along the lambdoid suture.

### Other features

These are as follows:

1. **Bregma**: It is a point at which coronal and sagittal sutures meet.
2. **Parietal eminence/tuber**: It is an area of maximum convexity of parietal bone.
3. **Vertex**: It is the highest point on the skull. It lies on the sagittal suture near its middle and is situated a few centimetres behind the bregma.
4. **Parietal foramen**: It is a small foramen in parietal bone near sagittal suture, 2.5–4 cm in front of lambda.
5. **Obelion**: It is a point on sagittal suture between the two parietal foramina.

### Norma occipitalis (Fig. 2.5 )

When the skull is viewed from behind, it appears convex upwards and on sides but flattened below.

**FIG. 2.5 ■** Norma occipitalis.

It presents the following features:

### Bones and sutures

The bones seen in this view are posterior portions of parietal bones, upper part of occipital bone, and mastoid parts of temporal bones. They are located as follows:

1. **Parietal bones** , superiorly one on each side.
2. **Occipital bone** (squamous part), inferiorly.
3. **Mastoid part of temporal bone** , inferolaterally on each side.

The sutures which unite these bones are as follows:

1. **Lambdoid suture** , between occipital and two parietal bones.
2. **Occipitomastoid suture** , between occipital and mastoid part of temporal bone.
3. **Parietomastoid suture** , between parietal and mastoid part of temporal bone.

### Other features

The other features to be noted on the posterior aspect of the skull are as follows:

1. **Lambda:** It is the point at which sagittal and lambdoid sutures meet.
2. **External occipital protuberance:** It is a median bony projection

about midway between the lambda and the foramen magnum. The most prominent point of the external occipital protuberance is called **inion** .

3. **Superior nuchal lines:** These are curved bony ridges passing laterally on each side from external occipital protuberance. In some cases, curved faint bony ridges are seen 1 cm above the superior nuchal lines. They are called **highest nuchal lines** .
4. **External occipital crest:** It is a vertical ridge between the external occipital protuberance and posterior margin of the foramen magnum.
5. **Inferior nuchal lines:** These are curved bony ridges passing laterally on each side from middle of the external occipital crest.
6. **Mastoid foramen:** It is present near the occipitomastoid suture.

### **Norma frontalis (Fig. 2.6 )**

In frontal view, the skull appears oval, being wider above and narrower below.

**FIG. 2.6 ■ Norma frontalis. P = prosthion**

The anterior aspect of the skull presents the following features:

1. Frontal region formed by frontal bone
2. Orbital openings
3. Prominences of the cheek formed by zygomatic bones

4. Bony external nose and anterior nasal aperture
5. Upper and lower jaws bearing teeth.

### Frontal region formed by frontal bone

The frontal region or the forehead is formed by the squamous part of the frontal bone. Below on each side of median plane, it articulates with the nasal bones. Frontal region presents the following features: superciliary arches, glabella, and frontal eminences. These are already described in [Chapter 1](#) .

### Orbital openings

These are the openings of two orbital cavities on the face. Each opening is present above and lateral to the anterior nasal aperture. It is quadrangular in shape and presents four margins, namely supraorbital, lateral, infraorbital, and medial.

1. The **supraorbital margin** is formed entirely by the frontal bone. At the junction of its sharp lateral two-third and rounded/ill-defined medial one-third, there is a notch called **supraorbital notch** (or foramen in some skulls), through which passes the supraorbital nerve and vessels.
2. The **lateral orbital margin** is formed by the frontal process of zygomatic bone and zygomatic process of frontal bone meeting at fronto-zygomatic suture, an important landmark.
3. The **infraorbital margin** is formed by the zygomatic bone laterally and the maxilla medially.
  - Below this margin, the maxilla presents an opening called **infraorbital foramen** through which passes the infraorbital nerve and vessels.
4. The **medial orbital margin** is ill-defined as compared to other margins. It is formed by the frontal bone above and the anterior lacrimal crest of the maxilla below.

### Prominences of the cheek formed by zygomatic bones (malar bones)

Each prominence is situated on the lower and lateral side of the orbit and rests on the maxilla. It is marked by a foramen called *zygomaticofacial foramen* .

## Bony external nose and anterior nasal aperture

The *bony external nose* is formed by the nasal bones and maxillae. It terminates in front and below as piriform aperture of the nose called *anterior nasal aperture* which is bounded above by the nasal bones, and laterally and below on each side by the nasal notches of the maxillae.

The two nasal bones articulate in the midline with each other at internasal suture, *posteriorly* with frontal process of maxilla and *superiorly* with frontal bone at the frontonasal suture. Anterior nasal spine is a sharp bony projection which marks the meeting of the two maxillae in the lower boundary of the anterior nasal aperture.

## Upper and lower jaws

The *upper jaw* is formed by two maxillae. On the anterior aspect, each maxilla presents:

- (a) A *zygomatic process* , which extends laterally and articulate with the zygomatic bone
- (b) A *frontal process* , which projects upwards and articulates with the frontal bone
- (c) An *alveolar process* , which carries the upper teeth
- (d) *Anterior surface of the maxilla* , which presents: nasal notch medially; infraorbital foramen 1 cm below the infraorbital margin; incisive fossa above the incisor teeth; canine fossa lateral to canine eminence produced by the root of canine tooth.

The *lower jaw* is formed by the mandible. The upper border, also called **alveolar process of the mandible** , carries the lower teeth (mandible is described in detail on page 26).

## Bones and sutures

As discussed, following bones are seen when skull is viewed from the front:

1. **Frontal bone** , forming the forehead.
2. **Nasal bones** (right and left), forming the bridge of the nose.
3. **Maxillae** (right and left), forming the upper jaw.
4. **Zygomatic bone** (right and left), forming the malar prominences.
5. **Mandible** , forming the lower jaw.

The **sutures** seen in this view are as follows:

1. Frontonasal
2. Internasal
3. Frontomaxillary
4. Zygomaticomaxillary.

## Other features

In addition to the earlier mentioned features, following features should be noted in median plane and lateral regions of the anterior aspect of the skull:

### 1. In the median plane lies 7 cranial points:

- (a) *Glabella* , a median elevation above the nasion and between the superciliary arches.
- (b) *Nasion* , a median point at the root of the nose where the internasal and frontonasal sutures meet.
- (c) *Anterior nasal spine* , a sharp bony projection in the median plane, in the lower boundary of the piriform aperture.
- (d) *Prosthion* , Midpoint on the alveolar margin of of the upper jaw between medial incisors.
- (e) *Symphysis menti* , a median ridge joining two halves of the mandible.
- (f) *Mental protuberance* , a triangular elevation at the lower end of symphysis menti.
- (g) *Mental point (gnathion)* , middle point of the base of the mandible.

### 2. In the lateral region (from above downwards):

- (a) *Frontal prominence* , a low rounded elevation above the superciliary arch.
- (b) **Three foramina lying in same vertical plane, namely,**
  - (i) *Supraorbital notch or foramen*, at the junction of medial one-third and lateral two-third of the superior orbital margin.
  - (ii) *Infraorbital foramen*, 1 cm below the infraorbital margin.
  - (iii) *Mental foramen*, below the interval between two premolar teeth.
- (c) An *oblique line on the body of the mandible* , extending between mental tubercle and lower end of anterior margin of ramus of the mandible.

## Norma lateralis (Fig. 2.7 )

When skull is viewed from its lateral aspect, it presents the following features.

**FIG. 2.7** ■ Norma lateralis.

## Bones and sutures

The **bones** seen on the lateral aspect of skull are frontal, parietal, occipital, temporal, sphenoid, zygomatic, mandible, maxilla, and nasal.

The **sutures** seen on this aspect of the skull are as follows:

1. **Coronal suture** (discussed previously on page 16).
2. **Parietosquamosal suture**, between parietal and squamous part of temporal bones.
3. **Lambdoid suture** (discussed previously on page 16).

## Other features

The other features to be noted on the lateral aspect of the skull are as follows:

1. **Temporal line:** It runs upwards and backwards from as posterosuperior border of the zygomatic bone, arches across the parietal bone where it splits into superior and inferior temporal lines. Traced behind, the superior temporal line fades away whereas prominent inferior temporal line curves downwards and forwards across the squamous part of the temporal bone as the **supramastoid**

**crest** , which is continuous with the posterior root of zygomatic process.

2. **Zygomatic arch:** It is a horizontal bar of bone formed by temporal process of zygomatic bone and zygomatic process of temporal bone. It presents two surfaces (outer and inner) and two borders (upper and lower). The upper border is continuous in front with the temporal line through posterosuperior border of the zygomatic bone, and behind with the *supramastoid crest* . The posterior end of lower border is marked by a tubercle called *tubercle of root of zygoma* . Here zygomatic process of temporal bone divides into anterior and posterior roots. The anterior root (*articular tubercle* ) passes medially forming anterior boundary of *mandibular fossa* . The posterior root forms lateral boundary of mandibular fossa and terminates behind into a small *postglenoid tubercle* .
3. **External acoustic meatus:** It is an opening just below the posterior root of the zygoma. Its anterior wall, floor and lower part of the posterior wall are formed by tympanic part of the temporal bone, whereas its roof and upper part of the posterior wall are formed by the squamous part of the temporal bone.
4. **Suprameatal triangle (triangle of McEwen; Fig. 2.22 ):** It is a small depression posterosuperior to the external auditory meatus.
5. **Mastoid process:** It is a mamma-like process of temporal bone extending downwards behind the meatus.
6. **Asterion:** It is a meeting point of parietomastoid, occipitomastoid, and lambdoid sutures.
7. **Styloid process:** It is a thin long bony process of temporal bone, anterolateral to the mastoid process below and behind the external auditory meatus. Its base is partly ensheathed by tympanic plate. It is directed downwards forwards and slightly medially.
8. **Temporal fossa:** It is a shallow depression on the side of the skull bounded above by the temporal line and below by zygomatic arch and supramastoid crest (laterally), and infratemporal crest of sphenoid (medially). It communicates with the infratemporal fossa through a gap between the zygomatic arch and the side of the skull.
9. **Pterion:** The region in the anterior part of the temporal fossa where four bones (frontal, parietal, squamous temporal, and greater wing of the sphenoid) meet to form an H-shaped suture is called **pterion** . It is situated 4 cm above the midpoint of the zygomatic arch.

10. **Surface markings of pterion ( Fig. 2.8 ):** It can be located on surface by placing the thumb behind the frontal process of zygomatic bone and two fingers above the zygomatic arch. The angle between the thumb and upper finger represents the site of pterion (Stile's method).
11. **Infratemporal fossa:** It is the region on the side skull, below the zygomatic arch. It is bounded medially by lateral pterygoid plate and laterally by ramus of the mandible. It is described in detail in [Chapter 10](#) .
12. **Pterygomaxillary fissure:** It is a triangular gap between the body of maxilla and lateral pterygoid plate of sphenoid. The infratemporal fossa communicates with the pterygopalatine fossa through this fissure. The pterygopalatine fossa is described in [Chapter 10](#) .

**FIG. 2.8 ■** Surface marking of pterion.

### **CLINICAL CORRELATION**

**Fracture of pterion:** Deep to pterion lies the anterior division of middle

meningeal artery (**Fig. 2.9 A**), which ruptures following a blow in this region to form an **extradural haematoma** (a clot formation between the skull bone and the dura mater [**Fig. 2.9 B**]). The clot, if big, may compress the brain leading to unconsciousness or even death. Therefore, it should be removed as early as possible by *trephination* or *craniotomy* .

**FIG. 2.9 ■** Pterion and extradural haematoma. ( **A** ) Relationship of anterior division middle meningeal artery to pterion; ( **B** ) extradural haematoma. (Source: Fig. 6.37, page 355, *Clinical and Surgical Anatomy* , 2e, Vishram

### **Norma basalis (Fig. 2.10 )**

For the sake of convenience of study, the norma basalis (undersurface of the skull) is divided into three regions/parts: anterior, middle, and posterior by two imaginary transverse lines, namely:

1. **Anterior transverse line** , which passes along the posterior, free margin of the hard palate.
2. **Posterior transverse line** , which passes along the anterior margin of the foramen magnum.

**FIG. 2.10 ■ Norma basalis.**

## Anterior part of norma basalis

It is formed by hard palate and alveolar processes of the maxillae.

Features in the anterior part of norma basalis are as follows:

1. **Alveolar arch:** The alveolar processes of two maxillae forms a U-shaped ridge of bone called *alveolar arch* , which bears the sockets for the roots of upper teeth.
2. **Hard palate:** It is formed by two pairs of bony processes: (1) palatine processes of maxillae in front (anterior two-third) and (2) horizontal plates of palatine bones behind (posterior one-third). The hard palate presents intermaxillary, interpalatine, and palatamaxillary sutures. The hard palate is described in detail in [Chapter 14](#) .

## Middle part of norma basalis

It extends from posterior margin of the hard palate to an imaginary transverse line that crosses the anterior margin of the foramen magnum.

Features in the middle part are as follows:

1. The median area presents:
  - (a) *Posterior border of vomer:* The two posterior nasal apertures (choanae) are separated by the posterior border of vomer.
  - (b) *Broad bar of bone:* It is formed by the fusion of the body of sphenoid and basilar part of the occipital bone. It is marked in the median plane by **pharyngeal tubercle** , a little in front of foramen magnum.
2. The lateral area presents:
  - (a) *Pterygoid process:* This process projects downwards from the junction between the body and greater wing of sphenoid behind last molar tooth. It divides into *medial and lateral pterygoid plates*, which are separated from each other by pterygoid fossa. Each plate has a free posterior border. The upper end of posterior border of medial pterygoid plate encloses a triangular depression called **scaphoid fossa** , and the lower end bears a hook-like process called **pterygoid hamulus** .
  - (b) Infratemporal surface of the greater wing of sphenoid presents:
    - (i) Four margins, namely
      - *Anterior margin* forms the posterior margin of inferior orbital fissure.

- *Anterolateral margin* forms the infratemporal crest.
  - *Posterolateral margin* articulates with the squamous part of temporal bone.
  - *Posteromedial margin* articulates with petrous part of temporal bone.
- (ii) Four foramina, all located along the posteromedial margin, namely
- *Foramen spinosum* , a small circular foramen at the base of spine of sphenoid.
  - *Foramen ovale* , a large oval foramen anterolateral to the upper end of the posterior border of the lateral pterygoid plate.
  - *Emissary sphenoidal foramen (foramen of Vesalius)* , a small foramen sometimes present between the foramen ovale and the scaphoid fossa.
  - *Canaliculus innominatus* , a very small foramen present between foramen ovale and spinosum. The structures passing through the above foramina are described in [Chapter 21](#) .
- (iii) *Spine of sphenoid* is a small sharp bony projection posterolateral to the foramen spinosum.

## CLINICAL CORRELATION

**Fracture/necrosis of spine of sphenoid:** Two nerves are related to the spine of sphenoid: *auriculotemporal nerve* on its lateral aspect and *chorda tympani* on its medial aspect.

Both these nerves carry secretomotor fibres to salivary glands: the *auriculotemporal nerve* to the parotid and *chorda tympani nerve* to the submandibular and sublingual salivary glands.

Both these nerves would be damaged following fracture or necrosis of the spine. This will result in decreased salivation and loss of taste sensations in the anterior two-third of the tongue.

- (c) *Sulcus tubae (groove for auditory tube)*: It is a groove between the posterolateral margin of greater wing of the sphenoid and petrous temporal bone. It lodges the cartilaginous part of the auditory tube.
- (d) *Inferior surface of the petrous temporal bone*: It is triangular

and presents an *apex*, which forms its anteromedial end. The apex is perforated by upper end of carotid canal and separated from the sphenoid by **foramen lacerum** .

(e) *Downward edge of tegmen tympani*: It divides the squamous tympanic fissure into petrotympanic and petrosquamous parts.

### Posterior part of norma basalis

It is behind the imaginary transverse line passing along the anterior margin of the foramen magnum.

Features in the posterior part are as follows:

1. The **median area** presents the following structures from backwards:
  - (a) Foramen magnum
  - (b) External occipital crest
  - (c) External occipital protuberance.
2. The **lateral area** presents:
  - (a) *Occipital condyles*: These are oval condylar processes, one on each side of foramen magnum.
  - (b) *Hypoglossal canal*: It is located anterosuperior to occipital condyle.
  - (c) *Condylar fossa*: It is small fossa located behind the occipital condyle. Sometimes it is perforated by a canal called *condylar (posterior condylar) canal*.
  - (d) *Jugular process of occipital bone*: It lies lateral to occipital condyle and forms the posterior boundary of jugular foramen.
  - (e) *Jugular foramen*: It is a large elongated foramen at the posterior end of the *petro-occipital suture* . Its anterior wall is hollowed out to form the jugular fossa.
  - (f) *Tympanic canaliculus*: It opens on the thin edge of the bone between the jugular fossa and the lower end of the carotid canal.
  - (g) *Stylomastoid foramen*: It is situated posterior to the root of the styloid process.

### N.B.

It is interesting to note that foramen ovale, foramen lacerum, and line of fusion of the body of the sphenoid with basilar part of occipital bone lie in same transverse line (Fig. 2.11 ).

Similarly, anterior border of mastoid process, stylomastoid foramen,

jugular foramen, and hypoglossal canal lie in the same transverse line (Fig. 2.11 ).

**FIG. 2.11** ■ Enlarged view of base of skull to show the features lying in the same imaginary transverse lines.

## Structures passing through various foramina, canals, and fissures on the outer aspect of skull AN 26.3

The total number of normal openings (foramina, canals, and fissures) in the skull is around 85, which provide passage to various nerves and vessels. Some of these are of little significance as they provide passage to minor neurovascular structures of no clinical significance. Attention should, therefore, be paid to those openings which provide passage to major neurovascular structures such as openings for: (1) spinal cord and vertebral arteries, that is, foramen magnum; (2) internal jugular vein, that is, jugular foramen; and (3) internal carotid artery, that is, carotid canal.

**In the basis cranii externa/norma basalis (inferior aspect of the skull)**

## **Lateral incisive foramina**

They are two in number, right and left, present in the lateral wall of the incisive fossa and lead to the floor of the nasal cavity through incisive canal. They transmit:

1. Greater palatine vessels (terminal parts).
2. Nasopalatine nerve (terminal part): only when the median incisive foramina are absent.

## **Median incisive foramina**

They are two in number, one present in the anterior and another in the posterior wall of the incisive fossa. They transmit:

1. Left nasopalatine nerve: passes through the one present in the anterior wall of the incisive fossa.
2. Right nasopalatine nerve: passes through the one present in the posterior wall of the incisive fossa.

## **Greater palatine foramen**

One, on each side, located in the posterolateral angle of hard palate. It transmits:

1. Greater palatine nerve.
2. Greater palatine vessels.

## **Squamotympanic fissure**

Present between tympanic part (plate) of temporal bone and squamous part of temporal bone (mandibular fossa), it is divided by a down-turned part of tegmen tympani (a part of petrous temporal bone) into *petrotympanic* and *petrosquamous fissures*.

1. Petrotympanic fissure transmits:
  - (a) *Chorda tympani nerve*: a branch of facial nerve.
  - (b) *Anterior tympanic artery*: a branch of the first part of the maxillary artery.
  - (c) Anterior ligament of the malleus.
2. **Petrosquamous fissure**: no structure passes through it.

## **Palatovaginal canal**

Present between upper surface of sphenoidal process of palatine bone and lower surface of vaginal process of sphenoid bone ([Fig. 2.26](#)). It transmits:

1. Pharyngeal nerve: a branch from the pterygopalatine ganglion.
2. Pharyngeal artery: a branch of the third part of the maxillary artery.

### **Vomerovaginal canal**

Present between lower aspect of ala of vomer and upper aspect of vaginal process of root of medial pterygoid plate.

If present, it provides passage to:

1. Pharyngeal nerve: a branch from the pterygopalatine ganglion.
2. Pharyngeal artery: a branch of the third part of the maxillary artery.

### **Pterygoid canal**

Present in pterygoid process of the sphenoid bone connecting anterior wall of foramen lacerum to pterygopalatine fossa. It transmits:

1. Nerve of pterygoid canal (Vidian's nerve).
2. Vessels of the pterygoid canal.

### **Carotid canal**

Located on inferior surface of the petrous temporal bone. It transmits:

1. Internal carotid artery with sympathetic plexus around it.
2. Internal carotid venous plexus connecting cavernous sinus and internal jugular vein.
3. Emissary vein connecting pharyngeal venous plexus and cavernous sinus.

### **Tympanic canaliculus**

Located on the bony crest between carotid canal and jugular fossa and transmits:

1. Tympanic branch of glossopharyngeal (Jacobson's nerve).

### **Mastoid canaliculus (Arnold's canal)**

Present in the lateral wall of the jugular fossa and transmits.

1. Auricular branch of vagus nerve (Alderman's nerve/Arnold's nerve).

### **Stylomastoid foramen**

Located between the roots of styloid and mastoid processes, at the anterior end of mastoid notch. It transmits:

1. Seventh cranial (facial) nerve.
2. Stylomastoid artery, a branch of posterior auricular artery.

### **In the norma occipitalis (posterior aspect of the skull)**

#### **Mastoid foramen**

Present on the posterior aspect of mastoid process near the occipitomastoid suture. It transmits emissary vein, connecting the posterior auricular vein with transverse sinus.

### **In the norma lateralis (lateral aspect of the skull)**

#### **Zygomaticotemporal foramen**

Present on the posteromedial surface of the zygomatic bone and transmits:

1. Zygomaticotemporal nerve.
2. Zygomaticotemporal artery.

#### **Pterygomaxillary fissure**

Present between lateral pterygoid plate and posterior surface of the maxilla and transmits:

1. Third part of the maxillary artery: from infratemporal fossa to the pterygopalatine fossa.
2. Maxillary nerve: second division of the 5th cranial nerve (V2).

#### **Sphenopalatine foramen**

Present in the roof of sphenopalatine fossa and transmits:

1. Nasopalatine nerve.
2. Sphenopalatine vessels.

#### **Greater palatine canal**

Present on either side between the palatine bone and maxilla. It transmits greater palatine nerve and vessels.

### **In the norma verticalis**

#### **Parietal foramen**

Present on the parietal bone near sagittal suture and transmits emissary vein, connecting superficial veins of the scalp to the superior sagittal sinus.

### **In the norma frontalis**

#### **Supraorbital foramen/notch**

Present on the supraorbital margin and transmits:

1. Supraorbital nerve, a branch of frontal nerve which, in turn, is a branch of ophthalmic division of the 5th cranial nerve.
2. Supraorbital vessels.
3. Frontal diploic vein.

#### **Superior orbital fissure**

See page 309, [Fig. 21.6 Chapter 21](#) .

#### **Inferior orbital fissure**

Present at the junction between floor and lateral wall of the orbit. It transmits:

1. Maxillary nerve
2. Infraorbital vessels
3. Zygomatic nerve
4. Vein connecting inferior ophthalmic vein with pterygoid venous plexus.

#### **Infraorbital foramen**

Present on the anterior aspect of maxilla, below the infraorbital margin and transmits:

1. Infraorbital nerve: continuation of maxillary nerve
2. Infraorbital artery: continuation of maxillary artery
3. Infraorbital vein.

## Zygomatico-orbital foramen

Present on the orbital surface of zygomatic bone and transmits zygomatic branch of the maxillary nerve.

## Mental foramen

Present on the external aspect of body of mandible below the interval between premolar teeth and transmits:

1. **Mental nerve:** a branch of inferior alveolar nerve
2. **Mental artery:** a branch of inferior alveolar artery
3. **Mental vein:** a tributary of inferior alveolar vein.

## Differences between male and female skulls

The sex-related differences of the skull are enumerated in [Table 2.1](#) .

 **TABLE 2.1**

### Differences between male and female skulls

	Male	Female
<b><i>Bones</i></b>	Thicker and heavier	Thinner and lighter
<b><i>Cranial capacity</i></b>	More	Less
<b><i>Muscular markings and ridges</i></b>	Well-marked, hence seen prominently	Not well-marked
<b><i>Superciliary arches</i></b>	Prominent	Not prominent
<b><i>Mastoid process</i></b>	Prominent	Less prominent
<b><i>Frontal and parietal tubers</i></b>	Less prominent	Prominent

## Craniometry

To compare skulls of different races and species, the physical anthropologists take various measurements of the skull. This process is called *craniometry* .

## Cranial points

The different points on the skull which are commonly used for taking measurements are as follows:

**In the midline:**

1. **Gnathion:** the midpoint of the chin at lower border of the mandible.
2. **Prosthion:** lowest point on the upper jaw between the central incisors.
3. **Acanthion:** anterior nasal spine.
4. **Nasion:** junction of nasal and frontal bones.
5. **Glabella:** midpoint at the level of superciliary arches.
6. **Bregma:** junction of coronal and sagittal sutures.
7. **Lambda:** junction of sagittal and lambdoid sutures.
8. **Opisthocranion (occipital point):** the most posteriorly projecting point on the occipital bone.
9. **Inion:** tip of external occipital protuberance.
10. **Opisthion:** central point on the posterior edge of the foramen magnum.
11. **Basion:** central point on the anterior edge of the foramen magnum.

**At the side of the skull:**

1. **Pterion:** region where frontal, parietal, greater wing of sphenoid and squamous part of temporal bones meet.
2. **Dacryon:** junction of lacrimomaxillary and frontomaxillary sutures.
3. **Gonion:** outer side of the angle of the mandible.
4. **Porion:** point on the posterior root of the zygomatic arch above the middle of the upper border of external auditory meatus.
5. **Asterion:** region where occipital, parietal, and temporal bones meet.

The calvarial part of skull is measured as follows:

- Maximal cranial length: from centre of glabella to opisthocranion
- Maximum cranial breadth: greatest breadth at right angle to the median plane
- Cranial height: from basion to bregma.

The **cephalic index** is calculated as follows:

$$\frac{\text{Maximum cranial breadth}}{\text{Maximum cranial length}} \times 100$$

### N.B.

- If maximum width of cranium is less than 75% of its maximum length, it is called *dolichocephalic skull* (long-headed individual).
- If maximum width of cranium is more than 80% of its maximum length, it is called *brachycephalic skull* (broad-headed individual).
- If ratio between maximum width of cranium and maximum length of cranium is between 75% and 80%, it is called *mesaticephalic* .

## Newborn skull

The striking feature of the newborn skull is the huge size of its cranium and relatively small size of its facial skeleton. In newborn, the facial skeleton forms approximately one-seventh of the cranium. The facial skeleton is small and consists of tiny collection of bones, clustered under the anterior part of the cranium ([Fig. 2.12](#) ).

**FIG. 2.12 ■** Foetal skull to show the location of fontanelles: ( **A** ) lateral aspect and ( **B** ) superior aspect.

The huge size of the **cranium** is because of fast development of the brain. The brain reaches 25% of its adult size at birth and 75% by the age of 4 years.

The size of **facial skeleton** at birth is because of rudimentary stage of the mandible and maxillae, noneruption of teeth and the small size of the maxillary air sinuses and the nasal cavity.

The following features of the newborn skull are clinically important:

1. **Fontanelles:** The bones of vault of skull are ossified in membrane. At birth, it is partly ossified and six unossified areas are seen between the bones which are called *fontanelles* (Fig. 2.12 ).

The fontanelles serve two important purposes, namely

- (a) Permit some overlapping of the skull bones (moulding) during childbirth.
- (b) Permits growth of the brain.

*Number of fontanelles:* There are six fontanelles at birth situated at the four angles of the parietal bones. Two are, therefore, median

(anterior and posterior) and four are lateral two (sphenoidal and mastoid) on each side. The **anterior fontanelle** is situated at the place where the two parietal bones and the two halves of the frontal bone come close together. It is largest and diamond shaped. It measures approximately 3–8 cm in length and 2–5 cm in breadth.

The **posterior fontanelle** is situated at the junction of the sagittal and lambdoid sutures. It is triangular in shape.

The **sphenoidal (anterolateral )** and **mastoid (posterolateral ) fontanelles** are situated at the sphenoid and mastoid angles of parietal bones. They are small and irregular. Posterior fontanelle closes soon after birth, lateral fontanelles close within a few weeks of birth and anterior fontanelle closes by 2 years of age.

### **N.B.**

All fontanelles close around birth except anterior fontanelle which closes by 2 years of age.

### **CLINICAL CORRELATION**

**The anterior fontanelle is largest and of great clinical significance.** The degree of tenseness of the membrane gives an index of the *intracranial pressure*. An abnormal depression of membrane indicates *dehydration* (insufficiency of the body fluids).

Furthermore, anterior fontanelle permits an access to the superior sagittal sinus as it lies just underneath it in the midline. Through its lateral angle, a needle may be passed into the lateral ventricle of the brain.

- 2. Tympanic cavity (middle ear cavity) and mastoid process:** The tympanum is a well-developed cavity at birth. The mastoid process does not begin to develop until the end of the second year. Before the mastoid process develops, the facial nerve is a subcutaneous structure and is in danger of being cut by an incision behind the ear, if it extends too far down. In adults, it is 2.5–3.8 cm from the surface, being pushed to the base of the skull by the development of mastoid process. In infants, the middle ear cavity is separated from temporal lobe of brain only by a thin strip of cartilage, uniting the squamous and petrous parts of temporal bone. This cartilaginous strip is very thin and lies underneath the dura mater and temporal lobe of the

brain. Therefore, infection of middle ear may spread through this cartilage to cause an extradural or temporal lobe abscess.

**3. Paranasal air sinuses:**

(a) Frontal air sinus does not exist at birth. It begins to develop during the first year and reaches its full development between 15th and 20th year.

(b) Maxillary air sinus is rudimentary at birth. It reaches its full development between 15th and 20th year.

4. **Mandible:** At birth, mandible is in two halves, united by the fibrous tissue at the symphysis menti.

5. **Frontal bone:** At birth, frontal bone is in two halves, united by the fibrous tissue in the midline. If it persists in the adult, it is called **metopic suture**.

6. **Basiocciput** and **basisphenoid:** Both these are united by a piece of hyaline cartilage (synchondrosis). It is responsible for growth of skull in length.

**N.B.**

All the bones of the skull are in the process of ossification at birth except styloid process and the perpendicular plate of ethmoid.

**Sutural (wormian) bones**

These are small irregular bones found in the sutures. They are formed by additional ossification centres that may occur in or near sutures. They are most numerous in the lambdoid suture. Sometimes they occur at fontanelles, especially in lambdoidal and mastoid fontanelles. In lambdoidal fontanelle, they may represent interparietal bone. An independent bone at lambda is called **Inca bone** or **Goethe's ossicle**. In the adult skull, they are most common at the lambda and at the asterion. Rarely, they may be seen at pterion (**epipteric bone**) and at bregma (**os Kerckring**). The wormian bones are common in hydrocephalic skulls.

**N.B.**

The sutural bones are usually small and bilateral. The Inca bone was common in the skull of Incas tribe and is still present in their Andean descendants.

**Study of individual skull bones AN 26.4**

The following account provides salient features of individual skull bones of both cranial and facial skeletons which are frequently asked in an oral examination.

### **Mandible (Fig. 2.13 ) AN 26.4**

The mandible is bone of the lower jaw. It is the largest, strongest, and lowest bone of the face and bears lower teeth.

**FIG. 2.13** ■ Whole mandible: ( A ) anterior view and ( B )

) posterior view. Figure in the inset above shows the shape of horse shoe.

### **Anatomical position**

In anatomical position, horizontally oriented 'U'-shaped body of mandible faces anteriorly with sockets for teeth, along its upper border and two vertically oriented plates – the rami – are kept posteriorly.

### **Parts (morphological features)**

The mandible is horseshoe-shaped and consists of **three parts** : a horizontally oriented anterior part called **body** and two vertically oriented posterior parts called **rami** (Figs 2.13 and 2.14 ). Each ramus has coronoid and condylar processes.

**FIG. 2.14 ■** Right half of the mandible: ( **A** ) external aspect and ( **B** ) internal aspect.

### Angle of the mandible

The meeting point between posterior and inferior borders of the ramus of mandible is called **angle of the mandible** .

### Body

The body of the mandible is U-shaped and it presents:

1. Two surfaces:
  - (a) *External surface*
  - (b) *Internal surface*
2. Two borders:
  - (a) *Superior border of the body* is called alveolar process. It bears sockets of lower 16 teeth.
  - (b) *Inferior border or base of the mandible* presents a small depression (**digastric fossa**) on either side near the median plane. It gives attachment to the anterior belly of the digastric.

### Features on external and internal surfaces of the body

The **outer surface of the body** of the mandible presents the following features (Figs 2.13 A and 2.14 B):

1. **Symphysis menti** (*mentum* = chin): It is a faint median ridge on external surface of the body. It marks the line of fusion of the two halves of the mandible at the age of 2 years. The symphysis menti expands below into a triangular elevation termed **mental protuberance**. It forms the **point of chin**, the base of which is limited on each side by the mental **tubercle**.
2. **Mental foramen**: It lies below the interval between the premolar teeth and provides passage to mental nerve and vessels.
3. **Oblique line**: It is the continuation of anterior border of the ramus. It runs downwards and forwards towards the mental tubercle.
4. **Incisive fossa**: It is a shallow depression just below the incisor teeth.

The **internal surface of the body** in each half of the mandible presents the following features (Figs. 2.13 B and 2.14 B):

1. **Inner aspect of symphysis menti** possesses four tubercles called **genial tubercles (mental spines)** arranged into two pairs: upper and lower. The upper pair provides attachment to genioglossus muscles and lower pair to geniohyoid muscles.
2. **Mylohyoid line** is a prominent oblique ridge that runs obliquely downwards and forwards from behind the 3rd molar tooth (approximately 1 cm below the alveolar border) to the symphysis menti below the genial tubercles.

3. **Mylohyoid groove** lies below the posterior end of the mylohyoid line. Mylohyoid nerve and vessels run in this groove.
4. **Sublingual fossa** is a shallow area above the anterior part of the mylohyoid line and lodges sublingual gland.
5. **Submandibular fossa** is a slightly hollowed out area below posterior part of the mylohyoid line and lodges submandibular gland.

### Muscles attached on the body of the mandible (Fig. 2.15 )

Various muscles attached to the body of the mandible are as follows:

1. **Buccinator:** arises from oblique line below the three molar teeth.
2. **Mylohyoid:** arises from mylohyoid line.
3. **Genioglossus:** arises from superior genial tubercle.
4. **Geniohyoid:** arises from inferior genial tubercle.
5. **Anterior belly of digastric:** arises from digastric fossa on the base of mandible close to symphysis menti.
6. **Platysma:** inserted into the base.
7. **Superior constrictor:** arises from the area above the posterior end of the mylohyoid line.
8. **Mentalis**
9. **Depressor labii inferioris**
10. **Depressor anguli oris .**

**FIG. 2.15 ■** Muscles attached to the mandible. ( A )

Lateral surface of right half of the mandible; ( **B** ) inner surface of left half of the mandible. GG, genioglossus; GH, geniohyoid.

## Ramus of the mandible

It is more or less a quadrilateral vertical plate of bone that projects upwards from the posterior part of the body.

### Features

The ramus presents the following features:

1. *Two surfaces* , namely:
    - (a) Lateral surface
    - (b) Medial surface
  2. *Four borders* , namely:
    - (a) Anterior
    - (b) Superior (it is notched to form **mandibular notch** )
    - (c) Inferior
    - (d) Posterior
  3. *Two processes*, namely:
    - (a) *Condylar process* , a strong upward projection from posterosuperior part. Its upper end is expanded to form head. Neck is the constricted part below head and presents a depression on its anterior surface called **pterygoid fovea** .
    - (b) *Coronoid process* , a flattened (side to side) triangular projection from anterosuperior part.
- Features on the medial and lateral surfaces of the ramus of the mandible are shown in [Figure 2.14](#) .
  - The **lateral surface** of ramus is flat and bears a number of oblique ridges produced by masseter muscle.
  - The **medial surface** of the ramus presents the following features:
    1. **Mandibular foramen**: It is located a little above the centre of ramus and leads into mandibular canal which runs downwards and forwards into the body to open on its external surface as **mental foramen** . It provides passage to:
      - (a) *Inferior alveolar nerve*: a branch of the posterior division of the mandibular nerve.

(b) *Inferior alveolar artery*: a branch from the first part of the maxillary artery.

(c) Inferior alveolar vein.

2. **Lingula** is a small tongue-shaped projection on anterior margin of the mandibular foramen.
3. **Mylohyoid groove** begins just below the mandibular foramen and runs downwards and forwards to reach the body of mandible below the posterior part of mylohyoid line.

### **Muscles attached to the ramus of the mandible (Fig. 2.15 )**

All the muscles of mastication are attached (inserted) into the ramus of mandible as follows:

1. **Masseter** is inserted into the outer surface of the ramus.
2. **Temporalis** is inserted into the coronoid process on its tip, anterior border and inner surface.
3. **Lateral pterygoid** is inserted into the pterygoid fovea present in front of the neck of the mandible.
4. **Medial pterygoid** is inserted into the inner surface of the ramus above the angle of the mandible.

### **Ligaments attached to the mandible (Fig. 2.16 )**

The following ligaments are attached to the mandible:

1. **Stylomandibular ligament** is attached to the angle of the mandible.
2. **Temporomandibular ligament** is attached to the lateral aspect of the neck of the mandible.
3. **Sphenomandibular ligament** is attached to the lingula of the mandible.
4. **Pterygomandibular raphe/ligament** is attached behind the last molar tooth to the upper end of mylohyoid line.

**FIG. 2.16 ■** Attachment of ligaments and nerves related to the mandible. ( **A** ) Lateral surface of the right half of the mandible; ( **B** ) medial surface of the left half of the mandible.

### **Nerves related to the mandible (Fig. 2.16 )**

The following nerves are related to the mandible:

1. **Lingual nerve** runs on the inner surface of the body close to the medial side of the root of the 3rd molar tooth.
2. **Inferior alveolar nerve** enters the mandibular foramen, and passes through the mandibular canal.
3. **Mylohyoid nerve** runs in the mylohyoid groove.
4. **Mental nerve** comes out of the mental foramen.
5. **Nerve to masseter** (masseteric nerve) runs through the mandibular notch.
6. **Auriculotemporal** nerve runs to the medial side of the neck.
7. **Marginal mandibular nerve** across the lower border of the mandible.

### **Differences between male and female mandibles**

These are listed in [Table 2.2](#) .

---

#### **TABLE 2.2**

## Differences between male and female mandibles

Features	Male mandible	Female mandible
Size	Larger and thicker	Smaller and thinner
Height of the body	Greater	Lesser
Angle of mandible	Everted	Inverted
Chin	Quadrilateral	Rounded
Inferior border of body of mandible	Irregular	Smooth
Condyles	Larger	Smaller

### Changes in the position of mental foramen with age (Table 2.3 )

These are as follows:

1. **At birth** , it is present below the sockets for deciduous molar teeth near the lower border.
2. **In an adult** , it gradually moves upwards and opens midway between the upper and lower borders.
3. **In old age** , it lies close to alveolar border because of resorption of alveolar process of the mandible due to loss of teeth.

### CLINICAL CORRELATION

**Fractures of the mandible:** The mandible occupies a prominent and exposed position of the facial skeleton; hence, it is commonly fractured following violent injuries viz., fall, trauma, etc.

**Sites of the fracture:** The mandible tends to fracture at one of the following sites (Fig. 2.17 ):

1. *Fracture neck of the mandible/fracture condyle of mandible* , as this is the weakest part of the bone (36%).
2. *Angle of the mandible* , because of abrupt curvature at this site (21%).
3. *Body of mandible* (in premolar and molar regions) (25%)
4. *Canine region of the body of mandible/parasymphyseal region* , because elongated root of canine tooth reduces the bony substance and makes the mandible weaker at this site (14%–15%).
5. *Symphysis*: due to twist/torsion and fall on the midpoint of chin (10%).

**FIG. 2.17 ■** Sites of the mandibular fracture: ( **A** ) neck of the mandible; ( **B** ) angle of the mandible; and ( **C** ) canine region.

### **N.B.**

- Most mandibular fractures are seen to occur in male patients with male and female ratio of 4.5:1.
- Flail mandible occurs because of bilateral fracture of mandible involving body, or symphysis.
- A fracture of the mandible usually involves two fractures one in each half of the mandible.
- Commonest site of fracture mandible is condyle (36%).

### **Age changes in the mandible (Fig. 2.18 )**

The important distinguishing features of mandible in different age groups are listed in [Table 2.3](#) .

- *In infants* and children, the body of mandible is mainly made up of alveolar part containing sockets for both deciduous and permanent teeth.
- *In adults* , alveolar and subalveolar parts of the body of the mandible are equally developed.
- *In old age* , teeth usually fall out and alveolar border is absorbed so that the height of the body is markedly reduced.

**FIG. 2.18** ■ Age-related changes in the mandible.

### TABLE 2.3

#### Distinguishing features of mandible in different age groups

Features	In children	In adult	In old age
Mental foramen	Present close to the inferior border of the body	Present midway between the upper and lower borders of the body	Present close to the upper border
Angle of mandible	140 degrees	110 degrees	140 degrees
Relationship between condylar and coronoid processes	Coronoid process above the level of condylar process	Condylar process projects above the level of coronoid process	Coronoid process projects above the level of condylar process
Mandibular canal	Runs near the lower border	Runs parallel with the mylohyoid line	Runs close to the upper border

## Ossification of the mandible

The mandible is formed by both membranous and endochondral ossification.

- Part of the mandible between mental and mandibular foramina ossifies in membrane from mesenchymal sheath of **Meckel's cartilage** first arch cartilage (mesenchymal ossification).
- Part of the mandible medial to mental foramen ossifies directly from Meckel's cartilage (*endochondral ossification* ).
- Coronoid and condylar processes ossify from secondary cartilages not related to Meckel's cartilage.

Originally the mandible develops as two distinct bones. Thus at birth, mandible consists of two halves united with each other at symphysis menti by cartilaginous nodules (mental ossicles). Later, the bony union takes place at the age of 1–2 year to form a single bone.

### N.B.

- The mandible is the second bone to ossify in the body. The centre in the mesenchymal sheath of Meckel's cartilage appears during the 7th week of intrauterine life.
- The other centres forming the mandible appear during the 10th week of intrauterine life.
- At birth, mandible consists of two halves connected at the symphysis menti by cartilaginous nodules (**mental ossicles**). The bony union starts from below upwards during the 1st year of the age and completed at the end of the 2nd year.

## Maxilla (Fig. 2.19 )

There are two maxillae, one on each side of midline between the orbit and upper teeth (Fig. 2.19 ). The two bones are fused together to form the upper jaw which plays an important role in mastication. They are irregular pneumatic bones.

**FIG. 2.19 ■** Right maxilla: ( **A** ) lateral aspect showing orbital, infratemporal and anterior surfaces and ( **B** ) medial aspect showing nasal surface and maxillary hiatus.

ZP = Zygomatic process, JC = jugular crest.

## Side determination

To determine the side, hold the maxilla in such a way (i.e., anatomical position) that its

- Alveolar process with sockets for teeth, faces downwards
- Longest frontal process is directed upwards
- Medial surface with large opening (maxillary hiatus faces medially)
- Concave nasal notch below frontal process faces medially

## Parts of the maxilla

The maxilla is the second largest bone of the face. It consists of **five parts** : a body and four processes (viz. frontal, zygomatic, palatine, and alveolar).

## Body of the maxilla

It is pyramidal in shape and contains a large cavity inside called **maxillary air sinus** .

***The body presents the following four surfaces:***

1. Nasal (medial) surface
  2. Orbital (superior) surface
  3. Infratemporal (posterior) surface
  4. Anterior (facial) surface.
1. **Nasal surface (base):** It forms the lateral wall of the nasal cavity and represents the base of the body of maxilla. It presents a large opening, **the maxillary hiatus** , which leads into maxillary sinus, a large air space within the body of the maxilla.
- The *maxillary hiatus* is the most prominent feature of the nasal surface .
  - In the articulated skull, the maxillary hiatus is reduced in size by the four bones, namely, ethmoid, lacrimal, inferior nasal concha, and palatine (for details, see [Chapter 17](#) , page 254).
  - In front of the hiatus is the **nasolacrimal groove** . It is converted into *nasolacrimal canal* by lacrimal bone and inferior nasal concha.
  - An oblique ridge present in front of the nasolacrimal groove is called **conchal crest** . It articulates with the inferior nasal concha.
  - A vertical groove, running obliquely in the posterior part of nasal surface is converted into *greater palatine canal* by a perpendicular plate of the palatine bone.

2. **Orbital surface:** It forms the major part of the floor of the orbital cavity. It presents infraorbital groove and canal for infraorbital nerve and vessels (see [Fig 19.2 A](#)).
3. **Infratemporal surface:** It forms the anterior boundary of infratemporal fossa. It is separated from the anterior surface by zygomatic process and bony ridge (jugular crest) that ascends to it from first molar socket. It presents few minute foramina for posterior-superior alveolar nerve and vessels.
4. **Anterior surface:** It forms the part of norma frontalis. Approximately 1 cm below the *infraorbital margin*, anterior surface presents the *infraorbital foramen* which transmits infraorbital nerve and vessels. Just above the alveolar process, anterior surface presents from medial to lateral: incisive fossa, canine eminence, and canine fossa. The canine eminence is caused by the root of canine tooth.

## Processes of the maxilla

Maxilla possesses the following four processes ([Fig. 2.20](#)):

1. Frontal process
  2. Zygomatic process
  3. Palatine process
  4. Alveolar process.
1. **Frontal process:** It projects upwards and articulates with the frontal bone. The thick frontal process lies in the line of buttress for dispersion of force of impact from teeth to the base of the skull.
    - Its lateral surface is divided into anterior and posterior parts by a vertical ridge called **anterior lacrimal crest**. The posterior part is grooved and forms a part of lacrimal fossa.
    - The medial surface of the frontal process is marked by a horizontal ridge called **ethmoidal crest**. It slopes downwards and forwards, and articulates with the middle nasal concha. An area below the ethmoidal crest forms the **atrium of the middle meatus**.
  2. **Zygomatic process:** It extends laterally to articulate with the zygomatic bone.
  3. **Palatine process:** It extends horizontally towards the medial side and forms the greater part of the hard palate.
  4. **Alveolar process:** It extends downwards and bears the sockets for roots of upper teeth. There are eight sockets. The socket for canine

tooth is deepest and sockets for molar teeth are widest. It is arched, being wider behind, to form the alveolar arch. The posterior part of the outer surface of alveolar arch opposite molar teeth gives origin to **buccinator muscle**.

**FIG. 2.20** ■ Processes of left maxilla.

### **N.B.**

The two maxillae are united in the anteromedian plane at the intermaxillary suture. The portion of the maxillae that carries the incisor teeth is sometimes termed **premaxilla**.

### **Articulations of the maxilla**

Each maxilla articulates with '9' bones:

- *Superiorly* with three bones: nasal, frontal, and lacrimal
- *Medially* with five bones: ethmoid, inferior nasal concha, vomer, palatine, and contralateral maxilla
- *Laterally* with one bone: zygomatic.

Differences between upper and lower jaws are given in the [Table 2.4](#) .

## **TABLE 2.4**

### **Differences between upper and lower jaws**

<b>Upper jaw</b>	<b>Lower jaw</b>
Formed by two bones – the maxillae	• Formed by a single bone – the mandible
Immobile	• Mobile
Articulates with 18 bones	• Articulates with only 2 bones
Articulate with other cranial bone by sutural joints	• Articulate with cranium by synovial joints

### **Ossification of maxilla**

The maxilla is formed by membranous ossification of two centres:

- One for **maxilla**
- One for **premaxilla** .

The centre for maxilla appears above canine fossa during 6th week of IUL.

The centre ossification of premaxilla appears around 8 week of IUL and soon (approximately 9 weeks) fuse with that of maxilla proper on that side.

### **CLINICAL CORRELATION**

#### **Fractures of maxilla (mid-face fractures)**

They occur because of fall on face from height, viz. a car accident, running into and colliding with the object, etc.

They are bilateral fractures, and usually categorized by using a system called *Le Fort's classification* ([Fig. 2.21](#) ).

#### **Le Fort's classification :**

1. *Le Fort level I fractures*: It is essentially a separation of hard palate from maxilla above. The transverse line of fracture passes just above the floor of nose, maxilla on either side, and pterygoid plates ([Fig 2.21 A](#)).
2. *Le Fort level II fractures*: It is essentially a separation of pyramidal-shaped mid-face from skull.  
In this, the fracture line passes through the root of the nose

below, floor of orbits, and then runs medial to and below the zygomatic bones towards the alveolar margin (Fig 2.21 B).

3. *Le Fort level III fractures (craniofacial disjunction)* : In this, the fracture line runs through the root of the nose, superior orbital fissures, and lateral walls of the orbits above the zygomatic bones.

There is complete separation of cranial skeleton from facial skeleton (Fig 2.21 C).

## Summary

*Le Fort I fracture*: floating palate (horizontal line of fracture)

*Le Fort II fracture*: floating maxilla (pyramidal line of fracture)

*Le Fort III fracture*: floating face/craniofacial disjunction (horizontal line of fracture)

**FIG. 2.21 ■** Bilateral fractures of the maxilla: ( **A** ) Le Fort I; ( **B** ) Le Fort II; and ( **C** ) Le Fort III.

### **N.B.**

Pterygoid plate is involved in all types of Le Fort fractures.

### **Temporal bone**

The temporal bone is an irregular pneumatic bone, situated on each side at the base and side of the skull (Fig. 2.22 ). It forms the most of the lower portion of side of the skull.

**FIG. 2.22 ■** Right temporal bone: external aspect. The figure in the inset on the right shows parts of temporal bone. Sq. P = squamous part in bone colour, PM = petromastoid part in red colour, TP = tympanic part in blue colour, SP = styloid part in green colour.

### **Parts**

It consists of the following four morphological parts:

1. Squamous part
2. Petromastoid part
3. Tympanic part
4. Styloid process.

For description purposes, the petromastoid part is generally subdivided into two parts: (1) petrous part and (2) mastoid part.

### Side determination

To determine the side of temporal bone, hold the temporal bone in such a way that:

- Thin transparent plate-like part is directed upwards and laterally
- Long-arched zygomatic process is directed anteriorly
- Wedge-shaped rock-like petrous part is directed medially
- External auditory meatus is directed laterally.

### Squamous part

It is thin, transparent, shell-like plate of bone which projects upwards to form the side of the skull. It presents external and internal surfaces; and superior and anteroinferior border and zygomatic process.

1. **External surface** forms the floor of temporal fossa and is grooved in its centre by the middle temporal artery.
  - The **zygomatic process** projects laterally from the lower and anterior parts of the temporal surface. It joins the temporal process of the zygomatic bone to form the **zygomatic arch** .
  - A deep cavity behind the articular eminence is called **mandibular fossa** . The mandibular fossa and articular tubercle are fundamental portions of the squamous part of the temporal bone.
2. **Internal surface** lies in contact with the temporal lobe of the brain. It is grooved by the anterior and posterior branches of the middle meningeal artery.

### Petromastoid part

It is located posteriorly and divided into two parts: petrous part and mastoid part.

1. **Petrous part:** It is the hardest (rock-like) part of the temporal bone.

It is seen on the base of skull and in the cranial cavity. It contains internal ear, middle ear, and mastoid antrum, which it safely protects. It also contains carotid canal for internal carotid artery.

◦The petrous part has a shape of a three-dimensional pyramid. It has a base, an apex, three surfaces, and three borders.

- The **base** is fused with the squamous part.
- The **apex** forms the posterolateral wall of the foramen lacerum.
- **Anterior surface** forms the posterior part of the middle cranial fossa. It presents five features ([Chapter 21](#) ).
- **Posterior surface** forms the anterior wall of the posterior cranial fossa. It presents three features ([Chapter 21](#) ).
- **Inferior surface** is seen at the base of the skull. It lies between the greater wing of sphenoid and basilar part of the occipital bone. It presents the lower opening of the carotid canal, jugular fossa, tympanic canaliculus, and a triangular depression in front of the jugular fossa.

The triangular depression in front of the jugular fossa lodges inferior ganglion of glossopharyngeal nerve. The apex of fossa presents an opening, which leads into a bony canal, the **cochlear canaliculus** which is traversed by aqueduct of cochlea/perilymphatic duct.

- **Superior border:** It is a long sharp crest which intervenes between middle and posterior cranial fossae. It is grooved by superior petrosal sinus. Its medial end is crossed by abducent nerve deep to petrosphenoid ligament (**ligament of Gruber** ).
- **Anterior border:** Its medial part articulates with greater wing of sphenoid and forms **sulcus tubae** on the undersurface of the base of the skull. Its lateral part joins squamous part at petrosquamosal suture.
- **Posterior border:** Its medial part articulates with the basilar part of the occipital bone and forms a groove which lodges the **inferior petrosal sinus** . Its lateral part forms the superolateral boundary of the jugular foramen.

2. **Mastoid part:** It lies below and behind the squamous part and contains *mastoid antrum* , which communicates with the middle ear cavity in the petrous part of the temporal bone. It ends below as

mastoid process. It encloses the *mastoid air cells* .

- On the medial side of the mastoid process, there is a notch called **digastric notch** for attachment to the posterior belly of digastric muscle.

### **N.B.**

*Mastoid air cells* : The mastoid process consists of a cortex of compact bone with a *honeycomb* of air cells underneath it. The air cells are small intercommunicating spaces which are continuous with the mastoid antrum and middle ear.

### **Types of Mastoid Processes:**

Depending on the air cell development (pneumatization), the following three types of mastoid processes have been described:

- *Pneumatic or cellular mastoid process*: In this, air cells are well-developed and the intervening septa are thin.
- *Diploic or mixed process*: The process consists of narrow spaces and few air cells.
- *Sclerotic or acellular process*: There are no cells or narrow spaces in the mastoid process. The antrum is small and sigmoid sinus is interposed.

### **CLINICAL CORRELATION**

- Mastoiditis and mastoid abscess: Middle ear infections often spread into mastoid antrum and mastoid air cells to cause *mastoiditis* and *mastoid abscess* .
- Bezold's abscess: When infection from mastoid abscess erodes the lateral wall of mastoid process and collects medial to attachment of sternocleidomastoid, it is called Bezold's abscess.

### **Tympanic part**

It is a thin, triangular curved plate of bone which forms the floor and anterior wall of the external auditory meatus. Anterior surface of the tympanic part forms the nonarticular part of the mandibular fossa and is related to the part of the parotid gland.

### **Styloid process**

It is a slender bony projection of approximately 1 inch length. It extends downwards and forwards from the undersurface of the tympanic plate. It is crossed externally by the facial nerve.

It gives attachment to three muscles (styloglossus, stylopharyngeus, and stylohyoid) and two ligaments (stylomandibular and stylohyoid).

**External acoustic meatus** (bony part) opens on the surface behind the mandibular fossa below the posterior part of the posterior root of zygoma and forms approximately two-third of the total length of the external auditory meatus.

The **suprameatal triangle (McEwen's triangle)** is a small depression posterosuperior to the external acoustic meatus.

It is bounded above by supramastoid crest, in front by posterosuperior margin of external acoustic meatus, and behind by a vertical tangent to the posterior margin of the meatus.

The mastoid antrum lies 1.25 cm deep to this triangle. A small bony projection called *suprameatal spine (spine of Henle)* may be present in the anteroinferior part of this triangle ([Fig. 2.22](#) ).

### **N.B.**

At birth, the tympanic cavity, tympanic membrane, mastoid antrum, ear ossicles, and internal ear – all are of the adult size.

### **Parietal bone**

The parietal bone ([Fig. 2.23](#) ) is a flat bone. It looks like a curved plate of bone, one on either side of sagittal suture which forms the major portion of the vault of the skull on the respective side. It is quadrilateral in shape.

**FIG. 2.23 ■** Right parietal bone: ( **A** ) external surface and ( **B** ) internal surface.

### Side determination

To determine the side, hold the bone in such a way that (1) outer surface is convex and inner surface is concave and showing vascular markings, and (2) elongated anteroinferior angle is directed downwards and forwards and shows a groove for middle meningeal artery on its internal surface.

## Parts

The parietal bone presents:

- **Two surfaces:** external and internal.
- **Four borders:** superior (sagittal), inferior, anterior, and posterior.
- **Four angles:** frontal, sphenoidal, occipital, and mastoid.

## Surfaces

The two surfaces of the parietal bone are as follows:

1. **External surface:** It is smooth and convex, and presents near its centre an elevation called parietal eminence or parietal tuberosity or parietal tuber – the most prominent feature of this surface. Below the parietal tuberosity, there are two curved lines called **superior and inferior temporal lines**. The parietal foramen is situated close to the posterior part of the superior border.
2. **Internal surface:** It is concave and overlies the parietal lobe of the cerebral hemisphere.
  - It presents the following features:
    - (a) *Sagittal sulcus* (only half) along the superior border, which lodges superior sagittal sinus.
    - (b) *Granular pits* by the side of sagittal sulcus, which lodge the arachnoid granulations.
    - (c) *Deep groove immediately behind the anterior border*, which lodges the anterior branch of the middle meningeal artery.
    - (d) An impression for posterior division of middle meningeal artery, which runs upwards from the middle of the lower border.
    - (e) *Transverse sulcus* across the posteroinferior angle, which lodges the sigmoid sinus.

## Borders

The four borders of the parietal bone are as follows:

1. **Superior (sagittal) border** articulates with similar border of opposite parietal bone to form sagittal suture.
2. **Inferior (squamosal) border** articulates with three bones. From

anterior to posterior, these are: (1) greater wing of sphenoid bone, (2) squamous part of temporal bone, and (3) mastoid portion of the temporal bone.

3. **Anterior (frontal) border** articulates with the frontal bone to form the coronal suture.
4. **Posterior (occipital) border** articulates with the squamous part of the occipital bone to form the lambdoid suture.

## Angles

The four angles of the parietal bone are as follows:

1. Anteroinferior (sphenoidal) angle – lies at pterion.
2. **Anterosuperior (frontal)** angle – lies at the bregma.
3. **Posteroinferior (mastoid)** angle – lies at the asterion.
4. Posterosuperior (occipital) angle – lies at lambda.

## N.B.

The anteroinferior (sphenoidal) angle projects downwards and forwards to a considerable extent.

## CLINICAL CORRELATION

- Occasionally, parietal bone is divided into two parts: upper and lower by an anomalous anteroposterior suture. The clinician may confuse this condition with a fracture. But it can be ruled out easily as the anomalous parietal suture is bilateral.
- The regenerating capacity of parietal bone is very poor because of lack of cambium layer in the periosteum.

## Zygomatic bone (cheek bone)

The zygomatic bone is also called **malar bone** because it forms the prominence of the cheek which is called *mala* in Latin. It connects the bones of face with those of cranium about the ear ([Fig. 2.24](#) ).

**FIG. 2.24 ■** Zygomatic bone (right side).

## Parts

The zygomatic bone consists of the following three parts:

1. A body
2. Two processes: frontal and temporal.

## Body

It presents three surfaces namely, orbital, lateral, and temporal.

1. **Orbital surface** forms a part of the lateral wall and floor of the orbit. It has a foramen, the zygomatico-orbital foramen, which transmits a zygomatic nerve.
2. **Lateral surface** is subcutaneous and presents a zygomaticofacial foramen through which zygomaticofacial nerve comes out.
3. **Temporal surface** forms the part of anterior wall of the temporal fossa and presents a zygomaticotemporal foramen, which transmits the zygomaticotemporal nerve.

## Processes

These are as follows:

1. **Frontal process:** It is a thick upward projection. It articulates with the zygomatic process of the frontal bone.
  - Its orbital surface presents a small tubercle near the orbital margin and 1 cm below the frontozygomatic suture called **Whitnall's tubercle**.
2. **Temporal process:** It extends backwards and joins the zygomatic process of the temporal bone to form the **zygomatic arch**.

### CLINICAL CORRELATION

The strong frontal process acts as a *line of buttress* for dispersion of force of impact to the frontal bone during mastication by the molar and premolar teeth.

## Ossification

The zygomatic bone ossifies in membrane by a single centre. Sometimes a fissure divides the bone into upper and lower parts. This is a usual feature in the Mongolian race, making their malar prominences flat; hence, it is known as **os japonicum**.

## Frontal bone

The frontal (L. *frontal* = forehead) bone ([Fig. 2.25](#)) is a flat bone, located in the region of the forehead. It is shaped like a cockleshell.

**FIG. 2.25 ■** Frontal bone: ( **A** ) external aspect and ( **B** ) inferior aspect.

### Anatomical position

In this position, large bowl-like vertical part is convex forwards and two thin horizontal orbital plates project backwards. The wedge-like nasal part with spine faces forwards and downwards.

### Parts

It consists of the following three parts:

1. Squamous part (largest part)
2. Nasal part (smallest part)
3. Orbital part.

### **Squamous part**

On each side, the lower part of the squamous part joins the orbital plate. The junction of these two forms the supraorbital margin. The squamous part presents external and internal surfaces.

The external surface above each supraorbital margin presents a curved elevation called **superciliary arch** . A rounded prominence between the medial ends of two superciliary arches is called **glabella** . Above the superciliary arch, the external surface displays an elevation called **frontal tuber** or **eminence** or **tuberosity** .

The internal surface of squamous part is deeply concave and presents a median bony ridge anteroinferiorly called **frontal crest** , which is continuous above with the sagittal sulcus.

The squamous part above superciliary arches contains two triangular cavities one on either side of median plane, called **frontal air sinuses** .

### **Zygomatic processes**

One on each side, it extends downwards and laterally from lateral end of the supraorbital margin. The zygomatic process joins the frontal process of the zygomatic bone. From posterior margin of each zygomatic process, temporal line curves upwards and backwards and splits into superior and inferior temporal lines.

### **Nasal part**

It is the small part of the bone which projects downwards between right and left supraorbital margins. It presents a serrated **nasal notch** , inferiorly which articulates with the two nasal bones one on each side of median plane and laterally on each side with frontal process of maxilla and the lacrimal bone.

### **Orbital part**

It consists of two orbital plates. Each orbital plate is a triangular curved plate of compact bone extending horizontally backwards from the supraorbital margin. It forms most of the roof of the orbit.

The two orbital plates are separated from each other by U-shaped

**ethmoidal notch** for accommodating cribriform plate of the ethmoid bone. The two orbital plates together form the *orbital part* .

## CLINICAL CORRELATION

- **Metopic suture:** The frontal bone ossifies in membrane. The primary centres appear one for each half of the frontal bone in the region of frontal tuberosity. At birth, frontal bone is made up of two halves, separated by a median *frontal suture (metopic suture)* . The union between the two halves begins at 2nd year and usually completes by the end of the 8th year. The remains of this suture in the adult are often seen in the region of glabella. It is termed **metopic suture** .
- The fracture of orbital plate of frontal bone leads to haemorrhage into the orbit. The haemorrhage acquires a triangular shape underneath the conjunctiva with apex towards the cornea and base towards the orbital margin.
- The frontal squama is prone to fracture. In neonates and infants, it is a depressed fracture (a dimple in the bone), whereas in adults it is a fissured fracture, that is, the depressed area always shows an irregular line of fracture at its periphery.

## Occipital bone

The occipital bone ([Fig. 2.26](#) ) is a flat bone which occupies posterior part of the skull. It is the main bone of occipital region. It is trapezoidal in shape and curved on itself like a shallow dish. It is characterized by the presence of large foramen magnum. It is the only skull bone which articulates with the cervical spine.

**FIG. 2.26 ■** Occipital bone: ( **A** ) external surface and ( **B** ) internal surface.

### Anatomical position

In this position, a very large oval foramen – the foramen magnum – is present at the bottom with wide bar of bone, the basilar part of the bone placed in front of foramen, the squamous part placed behind the foramen

with its convex surfaces directed posteriorly and two condyles one on either side of foramen.

## Parts

It consists of the following four parts:

- Squamous part
- Two condylar parts or lateral parts
- Basilar part (basiocciput).

## Squamous part

It is an expanded plate above and behind the foramen magnum. It presents two surfaces and three angles.

1. **External surface:** It is convex and shows the following features:
  - (a) *External occipital protuberance*, a median elevation at the point of its maximum convexity. The most prominent point of this protuberance is called inion.
  - (b) *External occipital crest*, a bony crest running downwards from external occipital protuberance to the foramen magnum.
  - (c) *Two superior nuchal lines*, one on each side, curve laterally from external occipital protuberance.
  - (d) *Two inferior nuchal lines*, one on each side curve laterally from the middle of the external occipital crest.
2. **Internal surface:** It is concave and shows the following features:
  - (a) *Internal occipital protuberance*, a bony elevation close to the centre.
  - (b) *Internal occipital crest*, a vertical bony crest which runs downwards from the internal occipital protuberance towards the foramen magnum. Near the foramen magnum, it splits to form a triangular depression called **vermian fossa**.
  - (c) Cruciate arrangement of four grooves, radiating from the internal occipital protuberance:
    - Sagittal sulcus/groove, runs upwards towards the superior angle; it is occupied by superior sagittal sinus.
    - Transverse sulcus/groove, one on each radiate towards the lateral angle; it is occupied by the transverse sinus.
    - A groove descends downwards towards the foramen magnum. It is occupied by the occipital sinus.

The small parts of grooves for sigmoid and inferior petrosal sinuses are also seen on the internal surface.

## CLINICAL CORRELATION

Occipital bone is a **membrano-cartilaginous bone**.

The *squamous part of occipital bone below the highest nuchal line* is ossified in cartilage from two centres – one on each side in the 7th prenatal week and soon joins with each other.

The *squamous part above the highest nuchal line* is ossified in membrane from two centres – one on each side in the 8th prenatal week and soon fuses with each other.

The two portions, upper and lower, of squamous part usually unite with each other in the 3rd month after birth when the baby starts holding its neck.

Sometimes the part above the highest nuchal line remains separate and persists as **interparietal bone (os interparietale** or Inca bone).

### Condylar parts

It is situated one on each side of the foramen magnum. The medial part bears occipital condyles. The lateral part, a quadrilateral plate projecting laterally from the posterior half of the occipital condyle is called **jugular process**.

The outer opening of **hypoglossal canal** transmitting hypoglossal nerve lies lateral to the anterior part of the occipital condyle.

The depression just behind the occipital condyle is called **condylar fossa** . Sometimes it presents a foramen in its floor called **posterior condylar canal** .

The anterior margin of jugular process presents a concave *jugular notch* which with similar notch on the petrous temporal bone forms the **jugular foramen** .

The superior surface of the condylar part presents the **jugular tubercle** .

### Basilar part (basiocciput)

It is a wide bar of bone which extends forward and upward from the foramen magnum and joined in front with the body of sphenoid by a layer of hyaline cartilage to form **spheno-occipital synchondrosis** (a primary cartilaginous joint).

The upper surface of the bar of bone formed by basisphenoid and basiocciput presents a shallow gutter, which slopes downwards and backwards from dorsum sellae to the foramen magnum. It is called **clivus** .

The inferior surface of the basilar part presents a *pharyngeal tubercle* in median plane, approximately 1 cm in front of the foramen magnum.

## CLINICAL CORRELATION

**Medicolegal importance of basisphenoid and basiocciput joint:** The *basisphenoid-basiocciput joint* is of medicolegal importance in assessing the age of the individual. It is the primary cartilaginous joint with plate of hyaline cartilage between the basilar part of the occipital bone and posterior part of the body of sphenoid bone. This cartilaginous plate is completely replaced by the bone (synostosis) by the 25th year of the age in males and 17 years in females. If there is no fusion or partial fusion in female, the age of girl should be below 17 years.

The basisphenoid basiocciput joint is responsible for growth of the skull in length.

## Sphenoid bone

The sphenoid bone ([Fig. 2.27](#)) is an unpaired irregular bone situated at the base of the skull. It resembles the shape of a butterfly or bat with outstretched wings.

**FIG. 2.27 ■** Sphenoid bone: ( **A** ) superior aspect and ( **B** ) posterior aspect. The figure in the inset shows the butterfly for its resemblance with sphenoid bone. LW = lesser wing, GW = greater wing, PP = pterygoid process, B = body

## Parts

It consists of the following seven parts:

- A body
- Two lesser wings
- Two greater wings
- Two pterygoid processes.

## N.B.

Two pterygoid processes represent the legs of the bat.

## Body

It is cuboidal in shape and contains a pair of sphenoidal air sinuses. The body presents six surfaces: superior, inferior, anterior, posterior and right and left lateral surfaces.

1. **Superior surface** presents the following features from before backwards:
  - (a) *Ethmoidal spine* , a triangular projection between the two lesser wings. It articulates with the posterior margin of the cribriform plate.
  - (b) *Jugum sphenoidale* , a flattened plate of bone behind the ethmoidal spine.
  - (c) *Sulcus chiasmaticus* , a shallow transverse groove, which leads on each side into optic canal.
  - (d) *Tuberculum sellae* , a horizontal elevation forming posterior limit of sulcus chiasmaticus. On each side, it presents small conical projections, the **middle clinoid process** .
  - (e) *Hypophyseal fossa* , a deep depression which lodges pituitary gland.
  - (f) *Dorsum sellae* , a square plate of bone which projects upwards

and presents a conical projection on each side called **posterior clinoid process** .

### **N.B.**

*Sella turcica* is collective name given to tuberculum sellae, hypophyseal fossa and dorsum sellae. It resembles a Turkish saddle.

2. **Inferior surface** presents the following three features:

- (a) *Sphenoidal rostrum*, a median ridge projecting downward. It occupies the groove between the alae of vomer.
- (b) *Sphenoidal concha*, a triangular plate of bone on each side of rostrum which articulates with the alae of vomer.
- (c) *Vaginal process* , a triangular bony shelf projecting downwards and medially from the base of each medial pterygoid plate. It helps to form *vomerovaginal and palatovaginal canals* .

3. **Anterior surface** presents the following features:

- (a) *Sphenoidal crest* , a vertical median ridge which articulates with the posterior border of the perpendicular plate of ethmoid to form part of nasal septum. On each side of the sphenoid crest lies the opening of sphenoidal air sinuses.
- (b) Upper vertical parts of sphenoidal conchae, it lies on each side of the crest.

4. **Posterior surface** is quadrilateral in shape and articulates by a plate of hyaline cartilage with the basiocciput.

5. Each **lateral surface** of the body joins with the greater wing of sphenoid (projecting laterally) and the pterygoid process (extending downwards). The lateral surface presents a groove called **carotid sulcus** produced by the internal carotid artery.

### **Lesser wings**

Each lesser wing arises from anterior part of the body of sphenoid by two roots. Between these two roots lies the optic canal. The projecting medial ends of the lesser wings are called **anterior clinoid processes** .

### **Greater wings**

Each greater wing spans out laterally from the side of the body forming the floor of the middle cranial fossa.

The greater wing has the following three surfaces:

1. **Upper surface:** It lies in the middle cranial fossa (for details, see middle cranial fossa on page 308).
2. **Lateral (infratemporal) surface:** It is divided into temporal and infratemporal surfaces by the infratemporal crest.
3. **Anterior (orbital) surface:** It lies at the lateral wall of the orbit and separates the superior orbital fissure from the inferior orbital fissure.

### Pterygoid processes

The pterygoid processes of sphenoid, one on either side descend perpendicularly from the region of sphenoid where body and greater wing join.

They are described on page 20.

### CLINICAL CORRELATION

- **Craniopharyngeal canal:** It is occasionally present in the floor of the pituitary fossa. It represents the remnant of *Rathke's pouch* which forms the anterior lobe of the pituitary gland.
- The observation of sella turcica in radiographs of skull is of great clinical significance because pathological changes in it reflect intracranial space-occupying lesions such as **pituitary tumour**.

### Ethmoid bone

The ethmoid bone is an unpaired and irregular fragile bone ([Fig. 2.28](#)) located between two orbital cavities. The ethmoid is so named because it possesses a perforated (sieve-like) plate called cribriform plate (Gr. *ethmoid* = sieve-like).

**FIG. 2.28 ■** Ethmoid bone. ( **A** ) Location of ethmoid in relation to nasal cavity, orbits, and maxillary sinuses; ( **B** ) superior view of ethmoid bone.

## Parts

The ethmoid bone consists of the following parts:

- Cribriform plate
- Crista galli
- Perpendicular plate
- Two labyrinths.

## Cribriform plate

The cribriform plate fills the ethmoidal notch between two orbital plates of the frontal bone and separates nasal cavities from the anterior cranial fossa. It has a number of small pores in it which transmit the filaments of olfactory nerve from the olfactory epithelium of the nasal cavity to the olfactory bulb of the brain.

## Crista galli

It is a triangular median crest on the upper surface of the cribriform plate. It resembles the crest on the head of *Gallus domesticus* (cock's comb), the red growth of flesh on the top of the head of a cock, and gives attachment to the anterior end of the falx cerebri.

## Perpendicular plate

It is a quadrilateral plate which projects downwards from the inferior surface of cribriform plate. It forms upper part of the nasal septum.

## Labyrinths

The labyrinths are the cuboidal bony boxes filled with air cells. The air cells, according to their location, are divided into three groups: anterior, middle, and posterior. The lateral surfaces of the labyrinth form the medial wall of the orbit and medial surface forms the lateral wall of the nasal cavity. The two shelf-like projections from the medial surface are called *superior* and *middle conchae* (remember: inferior concha is an independent bone).

## CLINICAL CORRELATION

In case of head injury, the blood-stained discharge of CSF from nose (CSF rhinorrhoea) indicates fracture of cribriform plate of the ethmoid in the anterior cranial fossa. It may result in anosmia (loss of smell) due to damage of olfactory nerves.

## Inferior nasal concha (turbinate bone)

There are two inferior nasal conchae. Each inferior nasal concha consists of lamina of spongy bone curled upon itself like a scroll. It projects downwards from the lateral wall of the nasal cavity. It is a curved bony plate and presents the following features:

- Medial and lateral surfaces
- Superior and inferior borders
- Anterior and posterior ends.

### Medial and lateral surfaces

The **medial surface** is convex. The **lateral surface** is deeply concave and forms the medial wall of the inferior meatus of the nose.

### Superior and inferior borders

The **superior border** is thin and irregular. Its anterior part articulates with conchal crest of maxilla and posterior part with conchal crest of the palatine bone. The middle part presents three processes from before backwards: lacrimal, maxillary, and ethmoidal.

The **inferior border** is thick and gently curved.

### Anterior and posterior ends

Both **anterior and posterior ends** are pointed. The posterior end is more narrow.

### CLINICAL CORRELATION

The inferior nasal concha is an independent facial bone. Its lacrimal process articulates with the margins of nasolacrimal groove of maxilla to form **nasolacrimal canal**. The surgical fracture of inferior nasal concha is sometimes needed to manage congenital defects of nasolacrimal groove.

### Palatine bone

There are two palatine bones ([Fig. 2.29](#)). They are flat, irregular bones, located one on either side, at the back of each nasal cavity. Each palatine bone is lodged between the maxilla in front and the pterygoid process of sphenoid bone behind. The palatine bone is so named because the two palatine bones form the posterior one-third of the hard palate.

**FIG. 2.29 ■** Palatine bone: ( **A** ) medial aspect and ( **B** ) posterior aspect of two palatine bones together.

## Parts

The palatine bone is L-shaped and consists of two plates:

1. Horizontal plate

## 2. Perpendicular plate.

It also possesses the following three processes:

1. Orbital process
2. Sphenoidal process
3. Pyramidal process.

### Horizontal plate

It projects medially and unites with its counterpart of opposite side to form the posterior one-fourth of the hard palate.

### Perpendicular plate

It is a vertical plate which is fixed with the posterior part of the medial surface of the maxilla. At its upper border, the perpendicular plate presents two processes: (1) sphenoidal process and (2) orbital process. Between the two processes, it encloses the **sphenopalatine notch**, which is converted into sphenopalatine foramen by inferior surface of the body of sphenoid. The lateral surface of the perpendicular plate presents a vertical groove, the *greater palatine groove*.

### Orbital process

It projects upwards and laterally from anterior part of upper border of the perpendicular plate, in front of sphenopalatine notch. It presents three articular and two nonarticular surfaces.

### Sphenoid process

It projects upwards and medially from posterior part of upper border of the perpendicular plate. It presents three surfaces and three borders.

### Pyramidal process

It projects posterolaterally from junction between the perpendicular and horizontal plates. The pyramidal process is pierced by the lesser palatine canals. The greater palatine canals run between the maxilla and the perpendicular plate of the palatine.

### CLINICAL CORRELATION

The Le Fort fractures of mid-facial skeleton always involve the perpendicular plates of palatine bones. The Le Fort I fracture involves the lower one-third of the perpendicular plates, whereas Le Fort II and Le Fort III fractures

involve the upper parts of the perpendicular plates of palatine.

## Vomer

The vomer (Fig. 2.30) is a thin quadrilateral plate of bone, which forms the posteroinferior part of the nasal septum.

**FIG. 2.30** ■ Vomer in relation to sphenoid and palatine bones. Note the formation of vomerovaginal and palatovaginal canals.

## Parts

The vomer presents the following features:

- Four borders
- Two lateral surfaces.

## Borders

The four borders are as follows:

1. **Superior border** is thick and grooved between the two diverging

alae. The groove fits over the sphenoidal rostrum.

◦The margin of ala intervenes between the body of sphenoid and vaginal process of medial pterygoid plate. The *vomerovaginal canal* is formed between the ala of vomer and vaginal process of medial pterygoid plate ([Fig. 2.30](#) ).

2. **Lower border** articulates with the nasal crest formed by the maxillae and palatine bones of the two sides.
3. **Posterior border** is free and separates the two posterior nasal apertures.
4. **Anterior border** is longest and slopes downwards and forwards. In its upper part, it articulates with the perpendicular plate of ethmoid and in its lower part with the septal cartilage.

### Lateral surfaces

The lateral surface on each side is covered by a mucous membrane and is marked by an anteroinferior groove for nasopalatine nerve and vessels.

### CLINICAL CORRELATION

- The vomer is involved in all three types of Le Fort fractures of mid-facial skeleton.
- The vomer is paper thin. A transverse fracture of vomer due to direct blow on the nose leads to deviated nasal septum (DNS).

## Cranial cavity AN 26.3

The cranial cavity is described in detail in [Chapter 21](#) .

## Bones of the neck

The bones of the neck are:

- Hyoid bone
- Cervical vertebrae.

### Hyoid bone

It is actually not a part of the skull. This U-shaped bone is located in front of the neck between the mandible and the larynx at the level of the 3rd cervical vertebra.

It is unique in the sense that it does not articulate with any other bone in the body, but it is suspended from styloid processes of temporal bones by stylohyoid ligaments (Fig. 2.31 ).

**FIG. 2.31 ■** Hyoid bone (anterior view). ( **A** ) Parts of hyoid bone; ( **B** ) muscle attachments.

### **Parts (Fig. 2.31 A)**

The hyoid bone consists of the following five parts:

- A body
- A pair of greater cornu (or horns)
- A pair of lesser cornu (or horns).

## Body

It is elongated and quadrilateral in form. The body presents two surfaces (anterior and posterior) and two lateral extremities:

1. The **anterior surface** is convex and faces forwards and upwards. Its upper part is crossed by a transverse line or ridge and in many cases a vertical median ridge divides the body into two lateral halves.
2. The **posterior surface** is smooth and concave. It faces backwards and downwards. The posterior surface of hyoid bone is separated from the epiglottis by the thyrohyoid membrane; a bursa intervenes between the bone and the membrane.
3. The **lateral extremities** of the body on each side are continuous with the greater cornu. In early life, the lateral extremities are connected with the greater cornu by a cartilage, but after middle life, they become united by a bone.

## Greater cornu

Each greater cornu projects backwards and upwards from the side of the body of the bone. They diminish in size from before backwards. Each cornu ends posteriorly in a tubercle.

When the neck is relaxed, two greater cornua can be gripped in vivo between index finger and thumb, and then the hyoid bone can be moved from side to side.

## Lesser cornu

Each lesser cornu is a small conical bony projection that is attached at the junction of the body and greater cornu. The stylohyoid ligament is attached to the tip of the lesser cornu and is sometimes ossified.

## N. B.

The hyoid bone provides attachment to a number of muscles; otherwise, it is of little functional significance (Fig. 2.31 B).

## CLINICAL CORRELATION

- In suspected cases of death, **examination of hyoid bone is of great medicolegal significance**, because fracture of hyoid bone in such cases suggests death by throttling or strangulation.

- The tip of greater cornu can be palpated in the relaxed neck near anterior border of sternocleidomastoid muscle, midway between laryngeal prominence and mastoid process. The lingual artery forms a loop above the greater cornua; hence, the latter forms an important surgical landmark for locating the lingual artery for ligation in radical surgery of the neck.

## Cervical vertebrae AN 26.5

There are seven cervical vertebrae, numbered 1–7 from above downwards. They are small in size as compared to thoracic and lumbar vertebrae as they have to carry less weight. They are identified by the presence of foramen in their transverse processes called **foramen transversarium** – the *cardinal feature of cervical vertebrae*.

The 3rd to 6th are **typical** because they have common features. The 1st, 2nd, and 7th are **atypical** because they possess special features for individual identification.

### Features of typical cervical vertebrae (Fig. 2.32 ) AN 26.5

The features of typical cervical vertebrae are as follows:

- The **b**ody:
  - (a) It is small.
  - (b) It is broader from side to side than from before backwards.
  - (c) Its superior surface is concave transversely with upward projecting lips on each side.
  - (d) The inferior surface on the anterior margin of the body projects downwards in front of the intervertebral disc, whereas the lateral margins are bevelled laterally to form the synovial joints with projecting lips of the vertebra below. These are called **uncovertebral joints (joints of Luschka)**.
- The **vertebral foramen** is triangular and larger than the body.
- The **superior and inferior** articular facets are flat:
  - (a) Superior facets are directed backwards and upwards.
  - (b) Inferior facets are directed forwards and downwards.
- The **transverse processes** are small and pierced by foramen transversarium. Each process has anterior and posterior roots, which end in tubercles called anterior and posterior tubercles. They are joined together by costotransverse bar. The costal element consists of

anterior root, anterior tubercle costotransverse bar, and posterior tubercle. The posterior root represents the transverse element of the developing vertebra.

- The spine is short and bifid.

**FIG. 2.32 ■** Typical cervical vertebra (superior aspect); inset on the right side shows the costal and transverse elements of the transverse process.

## Features of atypical cervical vertebrae (Fig. 2.33 ) AN 26.5

### First cervical vertebra (Fig. 2.33 A)

The 1st cervical vertebra is called **atlas** because it supports the globe of the head on its shoulders. According to Greek mythology, the Atlas is the God who supported the globe of earth on his shoulders.

It has following features:

1. It is ring shaped and has **no body** and **no spine** .

2. It consists of:

- (a) Right and left lateral masses connected by a short anterior arch and a long curved posterior arch.
- (b) Right and left transverse processes.

The **anterior arch** is marked in the median plane by the anterior tubercle on its anterior aspect, and an oval facet on its posterior aspect for articulation with the dens of the 2nd cervical vertebra to form median atlantoaxial joint.

The **posterior arch** forms two-fifth of the ring and its posterior aspect is marked by a median posterior tubercle. The upper surface of the posterior arch behind the lateral mass is marked by a groove which lodges the vertebral artery and the 1st cervical nerve.

The **lateral mass** presents the following features:

- (i) Its upper and lower surfaces bear superior and inferior articular facets, respectively.
  - ⊖ The superior articular facet is concave and elongated. It is directed upwards and medially to articulate with the corresponding condyle of the occipital bone to form the *atlanto-occipital joint*.
  - ⊖ The inferior articular facet is flat and circular. It is directed downwards, medially and backwards to articulate with the corresponding facet on the axis vertebra to form the lateral *atlantoaxial joint*.
- (ii) The medial surface of the lateral mass is marked by a small roughened tubercle to provide attachment to the transverse ligament of the atlas.
- (iii) The transverse processes project laterally from the lateral masses. They are strong and larger than that of other cervical vertebrae. The elongated transverse processes act as efficient **levers** for the rotation of the atlas vertebra.

### **N.B.**

The most important feature of atlas vertebra is the absence of its body. The body is absent because during development, the centrum of 1st cervical vertebra gets fused with the centrum of axis to form the dens. Thus, dens of axis vertebra represents the body of the atlas vertebra.

### **Second cervical vertebra (Fig. 2.33 B)**

The 2nd cervical vertebra is called **axis** because the atlas rotates like a wheel

around the **pivot provided** by the odontoid process (or dens) of 2nd cervical vertebra. It has the following features:

1. It possesses a strong tooth-like process projecting upwards from the body called **odontoid process** . The odontoid process represents the centrum (body) of the atlas, which has fused with the centrum of the axis vertebra.
  - The dens articulates anteriorly with the anterior arch of the atlas and posteriorly with the transverse ligament of the atlas. It provides attachment to the **apical ligament** at its apex and on each side below the apex to the **alar ligaments** .
2. The prominent anterior margin of the inferior surface of the body projects downwards to a considerable extent.
3. The spine is massive, i.e., it is large, thick, and very strong and deeply grooved inferiorly. Its tip is bifid.
4. The transverse processes are very small and lack the anterior tubercles. The foramen transversarium is directed upwards and laterally.
5. The laminae are thick and strong.
6. The superior articular facets on the upper surface of the body extend onto the pedicles. The massive pedicle overhangs the foramen transversarium laterally.

The superior articular facet is large, flat, and circular. They are weight bearing and encroach on the side of the body. It is directed upwards and laterally to articulate with the corresponding facet of the atlas.

The inferior articular facet lies posterior to the transverse process and is directed downwards and forwards to articulate with the 3rd cervical vertebra.

### **N.B.**

The old name of the axis vertebra was the *os cheloni* because of its resemblance to the head of a tortoise.

**FIG. 2.33** ■ Atypical cervical vertebrae. ( **A** ) Atlas vertebra (superior aspect); ( **B** ) axis vertebra (posterosuperior aspect); and ( **C** ) 7th cervical vertebra (superior aspect).

## 7th cervical vertebra (Fig. 4.33 & Table 2.5)

The 7th cervical vertebra is called **vertebra prominens** because its spine is very long and forms a prominent palpable projection in the lower part of the nuchal furrow.

The features of the 7th cervical vertebra are as follows:

1. Its spine is thick, long, and nearly horizontal. It is not bifid and ends in a tubercle.
2. The transverse processes are comparatively long and large and lack the anterior tubercles.
3. The foramen transversarium is relatively small and does not transmit the vertebral artery. It transmits only accessory vertebral vein.

The atypical features of 1st, 2nd, and 7th cervical vertebrae are summarized in [Table 2.5](#).

 **TABLE 2.5**

### Atypical features of 1st, 2nd, and 7th cervical vertebrae

<b>First cervical</b> (atlas)	(a) Ring-shaped (b) Absence of body (c) Absence of spine (d) Long transverse processes (e) Superior articular facets are concave and elongated; they are kidney-shaped; the inferior articular facets are more or less circular
<b>Second cervical</b> (axis)	(a) Presence of odontoid process (b) Transverse processes are small and lack the anterior tubercle (c) Anterior margin of the inferior surface of the body projects downwards to a considerable extent (d) Foramen transversarium is directed superolaterally (cf. in typical vertebrae, it is directed vertically) (e) Inferior surface presents a deep and wide inferior vertebral notch placed in front of the inferior articular

	process; the superior vertebral notch is shallow and is present behind the superior articular process
<b>Seventh cervical</b> (vertebra prominens)	(a) Spine is strong, long, and not bifid (b) Transverse process is relatively long and lacks the anterior tubercle (c) Foramen transversarium is relatively small

The cervical part of vertebral column and joints of neck are described in detail in [Chapter 7](#) on page 103.

## CLINICAL CORRELATION

- **Carotid tubercle:** The anterior tubercle of the transverse process of 6th cervical vertebra is large and called **carotid tubercle of Chassaignac** because the common carotid artery can be compressed against it, medial to the anterior border of sternocleidomastoid muscle.
- **Hangman's fracture** (see page 108, [Chapter 7](#)).
- *Luschka's joints* are commonest sites of osteophyte formation (**see page 105, [Chapter 7](#)**).
- **Klippel–Feil's syndrome** is a rare clinical condition in which two or more cervical vertebrae are fused and deformed congenitally.
- The congenital fusion of ring of atlas vertebra to the base of the occiput is called **occipitalization of atlas**. It is one of the most common abnormalities of the upper cervical vertebrae.

## Golden Facts to Remember

• <b>Os japonicum</b>	Lower part of bipartite zygomatic bone
• <b>Most commonly fractured cranial fossa</b>	Middle cranial fossa
• <b>Bones within bones</b>	Ear ossicles
• <b>Largest fontanelle</b>	Anterior fontanelle
• <b>Metopic suture</b>	Median suture above nasion between two halves of frontal bone in adult skull
• <b>McEwen's triangle</b>	A small triangular depression

(suprameatal triangle)	posterosuperior to the external auditory meatus (refer to page 19)
• Largest foramen of skull	Foramen magnum
• Most fragile and irregular bone of skull	Ethmoid
• Commonest site of fracture mandible	Canine region
• Cavities and bones within skull which are of full adult size at birth	Tympanic cavity, mastoid antrum, and ear ossicles
• Most dense part of temporal bone	Petrous part
• Largest primary cartilaginous joint of skull	Basisphenoid joint
• Largest and strongest bone of the face	Mandible
• Second largest bone of the face	Maxilla
• Last primary cartilaginous joint to ossify	Spheno-occipital joint at the base of skull which ossify by the age of 25 years in males

## CLINICAL CASE STUDY

Mr Ramu, a young taxi driver, suffered a head injury following a collision of his taxi with a truck. He became unconscious. He was taken to the emergency room by the traffic police. Radiographs of the skull were taken. The lateral view of skull radiograph revealed a fracture **in the region of temporal fossa** and an underlying epidural/extradural haematoma. He was referred to the Department of Neurosurgery where he was operated. The surgical procedure involved the removal of haematoma and ligation of ruptured artery the next day. Mr Ramu regained consciousness and he was discharged from the hospital. He was diagnosed as a case of **extradural haematoma**.

## Questions

1. What is extradural haematoma/epidural haematoma?
2. What is pterion?

3. Can this surface landmark be visualized or palpated? If not, then tell the method to locate it.
4. Name the vessels which ruptured to cause extradural haematoma and were ligated by the neurosurgeon.

### Answers

1. It is collection of blood between skull and dura mater underneath pterion.
2. **Pterion** is most important surface landmark in the region of temporal fossa (for details, refer to page 19 of this chapter).
3. No. It lies 4 cm above the midpoint of the zygomatic arch and can be located by Stile's method (see page 19).
4. Middle meningeal vessels.

---

# Chapter 3: Scalp, temple and face

---

## Specific learning objectives

---

**After studying this chapter, student should be able to:**

- Describe the scalp under the following headings: (a) definition and extent, (b) layers, (c) blood supply, (d) nerve supply and (e) surgical anatomy. **AN 27.1**
- Describe emissary veins with their role in spread of infection from extracranial veins to intracranial venous sinuses. **AN 27.2**
- Describe the muscles of facial expression and their nerve supply and actions. **AN 28.1, AN 28.6**
- Describe branches of facial nerve with distribution. **AN 28.4**
- Describe sensory innervation of face. **AN 28.2**
- Enumerate the components of lacrimal apparatus. **AN 31.4**
- Write short notes on: (a) occipitofrontalis muscle, (b) buccinator muscle, and (c) modiolus.
- Describe origin, course, and branches of facial artery. **AN 28.3**
- Describe formation, course, and tributaries of facial vein. **AN 28.3**
- Draw the labelled diagrams to show: (a) layers of scalp, (b) sensory innervations of head and face, and (c) layers of soft tissue in temple.
- Give the anatomical basis of: (a) dangerous area of scalp, (b) dangerous area of face, (c) black eye, (d) scalp wounds bleed profusely but heal quickly, and (e) Bell's palsy.
- Give anatomical basis of facial nerve palsy. **AN 28.7**
- Explain surgical importance of deep facial vein. **AN 28.8**
- Enumerate components of lacrimal apparatus. **AN 31.4**

The **scalp**, **temple**, and **face** are important areas of the head, and therefore, need to be studied thoroughly. The injuries are frequently inflicted in these areas. The nature of injuries varies from superficial wounds to deep cuts. The scalp and temple are covered by thick hair; hence, lesions at these sites go unnoticed for quite some time by the people.

Infection from these regions can travel inside cranial cavity through venous channels leading to fatal consequences.

The face is the commonest site for plastic surgery done to enhance the beauty or to repair congenital defects and defects produced by the injuries.

The simple inspection of face provides a substantial clue to a number of underlying bodily diseases. Also, the face being the exposed part of the body is prone to sun allergy and skin cancer.

## Scalp AN 27.1

The term *scalp* is applied to the soft tissues covering the vault of skull.

### Extent

It extends anteriorly up to the eyebrows (superciliary arches), posteriorly up to the superior nuchal lines, and laterally on each side up to superior temporal line (Fig. 3.1 ).

**FIG. 3.1 ■** Extent of the scalp.

Remember forehead is common to both scalp and face.

**N.B.**

According to some authorities, scalp extends laterally on each side, up to the zygomatic arch.

**Layers**

The scalp consists of five layers. From superficial to deep these are as follows (Fig. 3.2 ):

1. **S**kin
2. **C**onnective tissue (superficial fascia)
3. **A**poneurotic layer, (made up of occipitofrontalis muscle and its aponeurosis)
4. **L**oose areolar tissue
5. **P**ericranium.

**FIG. 3.2 ■** Layers of the scalp.

The sequence of the layers of scalp can be easily remembered by a perfect *mnemonic SCALP* derived by using initial letter of each layer.

These layers are described in detail in the following text.

## ***Skin***

- The skin of scalp is thick and hairy except over the forehead. It is firmly adherent to epicranial aponeurosis by dense connective tissue of superficial fascia, as in palms and soles. Being hairy, it contains maximum number of hair follicles and associated sebaceous glands. As a result, scalp is the commonest site of **sebaceous cysts** . It also contains numerous sweat glands.

### **N.B.**

It has been estimated that there are about 120,000 hairs on the scalp of an adult individual. About 20–100 hairs are lost daily and replaced concomitantly. The baldness (loss of hair) mainly affects males and few elderly females with high level of androgenic hormones in their blood.

## ***Connective tissue (superficial fascia)***

- The superficial fascia of the scalp is made up of dense fibrous connective tissue that firmly binds the skin to the underlying occipitofrontalis and its aponeurosis. Fibrous septa divide this layer into numerous small pockets containing lobules of fat. The blood vessels and nerves of the scalp lie in this layer. They enter it from below at the periphery.
- The walls of the vessels are adherent to the fibrous network; hence, when blood vessels are torn or cut during an injury, they are unable to retract and cause *profuse bleeding* . The bleeding, however, can be stopped by pressing against the underlying bone.

## ***Aponeurosis***

- This layer of scalp is formed by occipitofrontalis muscle and its aponeurosis.
- The occipitofrontalis muscle consists of four small bellies: two frontal bellies and two occipital bellies. Because greater part of this layer is formed by aponeurosis, it is called *aponeurotic layer* . The aponeurosis of occipitofrontalis muscle is also called *epicranial aponeurosis* or *galea aponeurotica* (Latin: *galea* = helmet).
- The wounds of the scalp do not gape unless epicranial aponeurosis is cut transversely because the aponeurosis is under tension in the anteroposterior direction by the tone of occipitofrontalis muscle.

## ***Loose areolar tissue***

- As the name indicates, this layer is made of loose areolar tissue. It serves as a natural plane of cleavage during craniotomy. This layer is traversed by emissary veins connecting veins in the second layer of scalp with intracranial dural venous sinuses.

### ***Pericranium***

- The fifth layer of scalp is formed by the periosteum of bones of vault of skull called *pericranium*. It is loosely attached to the bones and can be easily stripped but at sutures, it is firmly attached to sutural ligaments, which in turn attaches it to the endocranium (the periosteum covering inner aspect of the skull bones).

## **Further details**

### **Occipitofrontalis muscle (Fig. 3.3)**

#### ***Origin and insertion:***

1. The **frontal bellies** arise from skin and subcutaneous tissue over the eyebrows and root of the nose, run backwards to be inserted into epicranial aponeurosis in front of coronal suture. They have no bony attachment of their own. The deeper fibres of frontal belly merge with procerus, corrugator supercilii, and orbicularis oculi muscles.
  - The **frontal bellies** are longer, wider, and partly united with each other along their medial borders.
2. The **occipital bellies** arise from lateral two-third of the superior nuchal lines and extend forwards to be inserted into the epicranial aponeurosis. The two *occipital bellies* are small and separated from each other by a considerable gap. This gap is filled by epicranial aponeurosis.

**Nerve supply:** The occipital belly on each side is supplied by *posterior auricular branch of facial nerve*, whereas the frontal belly is supplied by *temporal branch of the facial nerve*.

#### ***Actions:***

1. Alternate contractions of frontal and occipital bellies move the scalp forwards and backwards over the vault of the skull.
2. Acting from above, contraction of frontal bellies raises the eyebrows as in surprise.
3. Acting from below, contractions of frontal bellies produce transverse wrinkles on the forehead as in fright.

**FIG. 3.3** ■ Occipitofrontalis muscle.

## CLINICAL CORRELATION

- **Surgical layers of the scalp:** First three layers of the scalp, that is, *skin, connective tissue layer, and aponeurotic layer* are firmly adhered to each other and cannot be separated from each other. These layers are termed **surgical layers of the scalp** and form the **scalp proper** ( **Fig 3.4** ).

✎ The layer of loose areolar tissue beneath the aponeurotic layer accounts for the free mobility of the scalp proper on the underlying bone. Further, it provides an easy plane of cleavage in injury and a plane in which blood from severed blood vessels can spread for a long distance. When the hairs are caught in machinery, the scalp proper is avulsed. It is in this plane that surgeons mobilize **scalp flaps** .

- **Black eye:** The blood and fluid collecting in the layer of loose areolar tissue following a blow on head tracks freely under the scalp producing generalized swelling over the dome of the skull, but cannot pass into either occipital or temple regions because of the bony attachments of the occipitofrontalis. The blood and fluid can, however, track forward into

the eyelids because occipitofrontalis has no bony attachment anteriorly (Fig. 3.4). This leads to formation of haematoma few hours after a head injury or cranial operation causing black discolouration of skin around the eyes, a condition called **black eye**.

It is important to note that the commonest cause of black eye is local violence, such as fist fight causing subcutaneous extravasation of blood into the eyelids.

- **Dangerous area of the scalp:** The layer of loose areolar tissue is called *dangerous layer of scalp* because blood and pus freely tend to collect in this layer. If pus collects in this layer, the infection may travel readily along emissary veins into the intracranial dural venous sinuses leading to their thrombosis, which may be fatal.
- **Safety-valve haematoma, cephalohaematoma, and caput succedaneum**
  - **Safety-valve haematoma:** Fracture of cranial vault in children may be associated with the tearing of dura mater and pericranium. In such cases, the blood from intracranial haemorrhage communicates with the subaponeurotic space of the scalp through the fracture lines. The signs of cerebral compression do not develop until the subaponeurotic space is fully filled with blood. For this reason, collection of blood in the fourth layer is called a *safety-valve haematoma*.
    - ¶ If cerebrospinal fluid collects in the subaponeurotic space, the condition is called *cephalhydrocele*.
  - **Cephalohaematoma** is a subperiosteal collection of blood. Because the periosteum of skull loosely covers the bones of skull except at the suture lines where it is firmly attached to the sutural ligaments the haematoma is bound by suture lines and assumes the shape of related bones. It is firm and its edges are well-defined. A cephalohaematoma is commonly found in the parietal region. It does not cross suture lines.
  - **Caput succedaneum** is a subcutaneous oedema over the presenting part of the baby's head at delivery. It takes place during the passage of head through the birth canal due to interference of the venous return.
    - ¶ It is the most common form of birth trauma of the scalp and usually occurs over the occiput and crosses the suture lines. The affected parts of the scalp feel soft and margins are partly

defined. Generally, the oedema subsides, in a few days. Oedema does cross suture lines as it is located superficial to galea aponeurotica.

**FIG. 3.4** ■ Sagittal section of the skull cap and overlying soft tissues. Note the migration of blood from fourth layer of the scalp (layer of loose areolar tissue) to the scanty subcutaneous tissue over orbicularis oculi.

## Nerve supply

### A. **Sensory supply of the scalp** (Fig. 3.5 )

- The scalp on each side of the midline is supplied by **eight sensory nerves** : four in front of the auricle and four behind the auricle. The nerves in front of the auricle are derived from trigeminal nerve, whereas those behind the auricle are derived from the 2nd and 3rd cervical nerves (Table 3.1 ).

### B. **Motor supply of the scalp**

- The scalp on each side of the midline is supplied by **two motor nerves**: one in front of the ear and one behind the ear; both these nerves are derived from the facial nerve (Fig. 3.3 ).
  - Nerve in front of the ear is *temporal branch of the facial*

- nerve . It supplies frontal belly of occipitofrontalis muscle.
- Nerve behind the ear is the *posterior auricular branch of the facial nerve* . It supplies occipital belly of occipitofrontalis muscle.

**FIG. 3.5** ■ Sensory supply of the scalp (shown in left half only).

**TABLE 3.1**

### Sensory nerves of the scalp

In front of the auricle (from before backwards)	Behind the auricle (from before backwards)
<b>Supratrochlear</b> , a branch of frontal nerve from ophthalmic division of trigeminal nerve	<b>Great auricular</b> , derived from ventral rami of 2nd and 3rd cervical nerves

<b>Supraorbital</b> , a branch of frontal nerve from ophthalmic division of trigeminal nerve	<b>Lesser occipital</b> , derived from ventral ramus of 2nd cervical nerve
<b>Zygomaticotemporal</b> , a branch of zygomatic nerve from maxillary division of trigeminal nerve	<b>Greater occipital</b> , derived from dorsal ramus of 2nd cervical nerve
<b>Auriculotemporal</b> , a branch of mandibular division of trigeminal nerve	<b>Third occipital</b> , derived from dorsal ramus of 3rd cervical nerve

## Arterial supply

The scalp has very rich blood supply. On each side of midline, it is supplied by **five arteries** : three in front of the auricle and two behind the auricle (Table 3.2 and Fig. 3.6 ).

### TABLE 3.2

#### Arteries supplying the scalp

In front of the auricle (from before backwards)	Behind the auricle (from before backwards)
<b>Supratrochlear</b> , a branch of ophthalmic artery from internal carotid artery	<b>Posterior auricular artery</b> , a branch of external carotid artery
<b>Supraorbital</b> , a branch of ophthalmic artery from internal carotid artery	<b>Occipital artery</b> , a branch of external carotid artery
<b>Superficial temporal</b> , a branch of external carotid artery	

**FIG. 3.6 ■** Arterial supply of the scalp. The area enclosed by blue dotted line shows the temporal flap.

### Site of entry of arteries in the scalp

1. **Supratrochlear artery** enters the scalp around supraorbital margin one-finger breadth lateral to the midline.
2. **Supraorbital artery** enters the scalp through supraorbital notch 2–3 cm lateral to the supratrochlear artery.
3. **Superficial temporal artery** (the smaller terminal branch of the external carotid) enters the scalp in front of the root of zygoma and divides into anterior and posterior branches.
4. **Posterior auricular artery** enters the scalp behind the root of the ear.
5. **Occipital artery** enters the scalp midway between the ear and the external occipital protuberance.

The first two arteries are the branches of ophthalmic artery from internal carotid artery, whereas the latter three arteries are the branches of external carotid artery.

The arteries of one side freely anastomose with one another. There is also cross-anastomosis between the arteries of both sides. **Thus, the scalp is also the site of potential collateral circulation between the external and internal carotid arteries.**

## CLINICAL CORRELATION

- **Scalp wounds bleed profusely but heal quickly:** This is due to high vascularity. The avulsed portions of scalp, therefore, should not be cut away rather they should be placed in position and stitched.
- **Flaps of scalp:** Because all the arteries supplying the scalp enter it from below at the periphery (i.e., from face and neck), the flaps of scalp during craniotomy are made by incisions given in the centre (top of skull) and reflected downwards towards the periphery; thereby preserving their blood supply. To ensure the blood supply of the scalp, skin incisions should be placed in such a way that the base of the flap incorporates the stem of one of the arteries supplying the scalp.
- **Control of scalp haemorrhage:** All the superficial arteries supplying the scalp ascend from face and neck; therefore, *life-threatening scalp haemorrhage* can be stopped as a first-aid measure, *by encircling the head just above the ears and eyebrows with a string or strong strap of cotton and tied tightly* .

## Venous drainage

The scalp on each side of the midline is drained by five veins. The veins of the scalp accompany the arteries and have similar names. These are as follows:

1. **Supratrochlear and supraorbital veins:** They join each other at the medial angle of the eye to form the **angular vein** , which continues downwards as the facial vein behind the facial artery.
2. **Superficial temporal vein:** It descends in front of tragus to enter the parotid gland where it joins the maxillary vein to form the **retromandibular vein** , which terminates by dividing into anterior and posterior divisions. The anterior division unites with the facial vein to form *common facial vein*, which drains into the internal

jugular vein.

3. **Posterior auricular vein:** It descends behind the auricle and unites with the posterior division of the retromandibular vein to form the *external jugular vein*, which drains into the subclavian vein.
4. **Occipital vein:** It terminates in the *suboccipital venous plexus* .

The veins of the scalp communicate with intracranial dural venous sinuses through emissary veins.

### CLINICAL CORRELATION

In infants, the veins of the scalp are easily seen deep to the skin; hence, they are the favoured sites for **intravenous infusion** .

### Emissary veins AN 27.2

They are thin walled valveless veins which connect extracranial veins with the intracranial dural venous sinuses by passing through foramina in the cranium.

#### Examples

On each side of the midline in the region of the scalp two sets of main emissary veins are encountered, namely:

1. **Parietal emissary vein** , which passes through parietal foramen and communicates between scalp veins and superior sagittal sinus.
2. **Mastoid emissary vein** , which passes through mastoid foramen and communicates between occipital and posterior auricular veins with the sigmoid sinus.

#### Other emissary veins

- *Frontal emissary vein* – passes through foramen caecum to connect the veins of nasal cavity with superior sagittal sinus.
- *Condylar emissary veins* – passes through posterior condylar canal and connect the suboccipital venous plexus with sigmoid sinus.

#### Functions of emissary veins

- Provide collateral pathways in case of obstruction of dural venous sinuses.

- Provide selective cooling of brain.

### CLINICAL CORRELATION

The emissary veins provide route for transportation of infection between extracranial and intracranial spaces.

Therefore, knowledge of their location and variation is of great surgical significance.

### Diploic veins

The diploic veins are large, thin walled valveless veins present in the diploe between outer and inner tables of skull bones. They described in detail in [Chapter 21](#) , [Fig. 21.3](#) .

### CLINICAL CORRELATION

Diploic veins are thin walled. They are devoid of valves and drain the diploë of some cranial bones. They begin to develop with diploë at about 2 years of age.

Radiologically, they may be seen as relatively transparent bands, 3–4 mm wide.

### Lymphatic drainage

The lymphatics from anterior part of the scalp except the lower half of the forehead drain into ***preauricular (or superficial parotid) lymph*** nodes situated on the surface of the parotid gland.

The lymphatics from posterior part of the scalp drain into ***posterior auricular (mastoid) and occipital lymph*** nodes .

## Temple

The shallow area on the side of the skull between the superior temporal line and zygomatic arch is called as temporal fossa. This fossa is mainly occupied by temporalis muscle. It is popularly known as *temple* .

The name temple is supposedly derived from the fact that with age (i.e., time) greying of hair occurs first in this area (tempus = time).

### Layers of soft tissue in the temple

There are ***six layers*** of soft tissue in the region of temple. From superficial to deep, these are ([Fig. 3.7](#) ) as follows:

1. Skin
2. Connective tissue
3. Extension of epicranial aponeurosis
4. Temporal fascia
5. Temporalis muscle
6. Pericranium.

#### *Skin and connective tissue*

- These two layers are same as in the region of the scalp.

#### *Extension of epicranial aponeurosis*

- It gives origin to the auricularis anterior and auricularis superior muscles of the auricle.

#### **Temporal fascia**

- It forms a roof over temporal fossa. It is attached above to the temporal line and below to the zygomatic arch.
- Inferiorly, the temporal fascia splits into two layers, which are attached to the inner and outer lips of the zygomatic arch. A small gap between the two layers contains: (1) fat, (2) a branch from superficial temporal artery, and (3) zygomaticotemporal nerve.
- The superficial surface of temporal fascia is related to: (1) superficial temporal vessels, (2) auriculotemporal nerve, and (3) temporal branches of the facial nerve.
- The deep surface of temporal fascia gives origin to some fibres of temporalis muscle.

#### **Temporalis muscle**

- This large fan-shaped muscle arises from the floor of the temporal fossa and inner aspect of the temporal fascia. Its fibres converge inferiorly and pass deep to the zygomatic arch to be inserted into the coronoid process of mandible. (It is described in detail in [Chapter 10](#) .)

#### **Pericranium**

- This layer is same as in the region of the scalp.

**FIG. 3.7** ■ Layers of the soft tissue in the temple.

## CLINICAL CORRELATION

**Temporal fascia as a graft:** The temporal fascia is silvery-white thick fibrous sheet, which is more or less aponeurotic in character. *It is the thickest fascia in the body.*

Morphologically, it represents a shell of a bone. In some species (e.g., tortoise), it is replaced by bone to make the temporal fossa a bony tunnel.

The temporal fascia is used as a graft by ENT surgeons for **tympanoplasty/myringoplasty** (repair of the tympanic membrane).

# Face

The face is the frontal aspect of the head possessing eyes, nose, and mouth. It extends superiorly up to the hairline, inferiorly up to the chin and base of the mandible and on each side up to the auricle. The forehead is common to both the face and the scalp. It is the site for emotional expression and verbal communication.

For proper understanding of anatomy of the face, one should first study the features on the anterior aspect of the skull (norma frontalis) described in [Chapter 2](#) and living anatomy described in [Chapter 1](#).

## Skin of the face

The skin of the face is **thick**, **elastic**, and **very vascular**. It contains large number of **sweat and sebaceous glands**. The sweat glands help to regulate the body temperature, whereas sebaceous glands keep the face oily by their secretion. The skin of face is lax except on the nose where it is firmly attached to the underlying cartilages and provides insertion to the muscles of facial expression.

## CLINICAL CORRELATION

**Facial skin flaps:** Because the blood supply to the skin of the face is profuse, it is rare in plastic surgery for skin flaps to necrose in this region. The laxity of greater part of skin facilitates rapid spread of oedema in the region of the face. Face is also the common site for acne because of the presence of large number of sebaceous glands in this region.

## Cleavage lines of skin in the face

The direction of cleavage lines in the face varies regionally ([Fig. 3.8](#)). However, these lines frequently (but not always) coincide with natural wrinkle lines of the face. The natural wrinkle lines result from repeated folding of the skin perpendicular to the long axis of the underlying contracting muscles of facial expression. They become prominent in the elderly because of loss of youthful skin elasticity.

**FIG. 3.8 ■** Lines of cleavage in the head and neck region: ( **A** ) front view and ( **B** ) lateral view.

When the lesions of skin, namely scars, pigmented patches, and skin cancers are excised, it is important to give incisions along the long axis of natural wrinkle lines and the lesion should be enclosed in an ellipse, if the resulting scar is to be aesthetically acceptable.

### **Superficial fascia**

It contains muscles of facial expression, vessels and nerves, and variable amount of fat. The fat is absent in the eyelids but is well developed in cheeks forming *buccal pad of fat* , which provides rounded contour to cheeks. The buccal pads of fat are very prominent in infants in whom they help in suckling the milk and are called *suctorial pad of fat* .

### **Deep fascia**

The **deep fascia is absent in the region of face** except over the parotid gland and masseter muscle, which are covered by ***parotidomasseteric fascia*** . The absence of deep fascia in the face is essential for the facial expression.

## **Muscles of facial expression/superficial muscles of face** **AN 28.6**

The muscles of facial expression are embedded in the superficial fascia. Most

of them arise from bones of the skull and are inserted into the skin. They bring about different types of facial expressions, hence the name ***muscles of facial expression***, the actions of many of them are implied by their names (Fig. 3.9).

**FIG. 3.9 ■** Muscles of the facial expression: ( **A** ) sites of bony attachment and ( **B** ) position in the face. Masseter and temporalis (muscles of mastication) are also shown. T, temporalis.

## Characteristic Features of the Muscles of Facial Expression AN 28.6

The characteristics of the muscles of facial expressions are as follows:

1. They lie in superficial fascia and inserted into the skin.
2. Morphologically, they represent the specialized members of the subcutaneous muscle called ***panniculus carnosus*** of lower animals.
3. Embryologically, they ***develop from mesoderm*** of 2nd pharyngeal arch, hence supplied by facial nerve, the nerve of 2nd arch.
4. Functionally, they perform all important functions of ***non-verbal communication*** such as showing anger, happiness, sadness etc.

## 5. Closing and opening the orifices in the region of the face.

### Nerve supply

All the muscles of facial expression are supplied by facial nerve ([Fig. 3.12](#)).

### Location and function

The facial muscles are arranged in groups around the orifices of mouth, eye, and nose as sphincters and dilators of these orifices.

In addition to regulating the opening and closing of these orifices, as mentioned earlier, they produce different types of facial expressions ([Table 3.3](#)). To perform fine movements of facial expressions, the facial muscles have *small motor units*.

 **TABLE 3.3**

### Facial muscles and emotional expressions

Emotional expression	Presenting features	Facial muscle/muscles
<b>Surprise/horror/fright</b>	Transverse wrinkles of the forehead	Frontalis
<b>Frowning</b>	<ul style="list-style-type: none"><li>• Vertical wrinkles of the forehead</li><li>• Transverse wrinkle across the root of nose</li></ul>	<ul style="list-style-type: none"><li>• Corrugator supercilii</li><li>• Procerus</li></ul>
<b>Anger</b>	<ul style="list-style-type: none"><li>• Dilation of the anterior nasal aperture</li><li>• Depression of lower mobile part of the nasal septum</li></ul>	<ul style="list-style-type: none"><li>• Dilator naris</li><li>• Depressor septi</li></ul>
<b>Laughing</b>	<ul style="list-style-type: none"><li>• Angle of mouth drawn upwards and laterally</li><li>• Accentuation of</li></ul>	<ul style="list-style-type: none"><li>• Zygomaticus major</li><li>• Levator labii</li></ul>

	nasolabial fold • Elevation and eversion of the upper lip	superioris • Levator anguli oris and zygomaticus minor
<b>Sadness/sorrow/grief</b>	Angle of mouth drawn downwards and laterally	Depressor anguli oris
<b>Grinning</b>	Retraction of angle of the mouth laterally	Risorius
<b>Disdain/doubt</b>	Puckering of the chin, protrusion of lower lip	Mentalis
<b>Worry</b>	Skinfolds radiating laterally from lateral angle of the eye	Orbicularis oculi
<b>Irony</b>	Angle of the mouth drawn downwards and somewhat laterally	Depressor labii inferioris

Though all these muscles are important for facial expression, students are advised not to burden their memory with their attachments. However, they should appreciate the importance of *orbicularis oculi*, *orbicularis oris*, and *buccinator* for the serious consequences following their paralysis.

### **N. B.**

In addition to muscles around the eye, nose, and mouth, the muscles of facial expression also include the muscles of scalp, auricle, and the subcutaneous muscle of the neck – the platysma.

### **Muscles around orifice of the eye**

These include:

1. Orbicularis oculi
2. Corrugator supercilii
3. Frontalis
4. Levator palpebrae superioris.

### **Orbicularis oculi**

It consists of three parts: orbital, palpebral, and lacrimal.

1. **Orbital part** arises from medial palpebral ligament, frontal process of maxilla, and adjoining part of the frontal bone. The fibres form complete elliptical loops on and around the orbital margin, without interruption before returning to their point of origin.  
*◦It closes the eye tightly to protect the eye from intense light and dust particles. It is also used by people for winking.*
2. **Palpebral part** arises from medial palpebral ligament and sweeps laterally over upper and lower eyelids to be inserted into the lateral palpebral ligament. A small group of fibres called *ciliary bundle* lies along the margins of both eyelids.  
*◦It closes the eyelids gently as in sleep or in blinking.*
3. **Lacrimal part** lies behind the lacrimal sac. It arises from lacrimal crest of lacrimal bone and lacrimal fascia forming a sheath of lacrimal sac that passes laterally in front of tarsal plates of both eyelids to be inserted into the lateral palpebral raphe.  
*◦It dilates the lacrimal sac by exerting traction on the lacrimal fascia, thus helping in the drainage of lacrimal fluid.*

## CLINICAL CORRELATION

- **Crow's feet:** The contraction of entire orbicularis oculi draws the skin of forehead, temple, and cheek towards lateral angle of the eye, producing radiating skinfolds from lateral angle of the eye, which may be a permanent feature in some old people forming the so called *crow's feet*.
- **Ectropion:** The paralysis of orbicularis oculi results in drooping of the lower eyelid (ectropion) causing spilling of tear on the cheek (epiphora).

## Corrugator supercilii

It arises from the medial end of the superciliary arch, passes laterally and upwards to be inserted into the skin of the eyebrow above the middle of the supraorbital margin.

It drags the eyebrow medially and downwards producing vertical wrinkles on the forehead as in frowning, an expression of annoyance.

## Frontalis

It is already described in the section on scalp. The frontalis elevates the eyebrows and produces transverse wrinkles on the forehead as an expression of surprise, horror, or fright.

## Levator palpebra superioris

It is not a muscle of the face but one of the orbital muscles, hence described in detail under orbit ([Chapter 19](#)). Levator palpebrae superioris is an antagonist to the sphincteric action of palpebral part of orbicularis oculi. It elevates the upper eyelid.

## Muscles around the nasal cavity

The muscles associated with nasal cavity are as follows:

1. Procerus
2. Nasalis
3. Depressor septi.

These muscles are poorly developed because anterior nares are open.

### Procerus

It arises from nasal bone, passes upwards to be inserted into the skin of the lower part of the forehead.

*It produces transverse wrinkles across the bridge (root) of the nose as in frowning.*

### Nasalis

It consists of two parts: transverse part called **compressor naris** and alar part called **dilator naris**.

1. Compressor naris arises from maxilla close to the nasal notch, passes upwards and medially to form an aponeurosis across the bridge of nose where it becomes continuous with its counterpart on the opposite side.

*It compresses the nasal aperture.*

2. Dilator naris arises from maxilla from the margin of the nasal notch and inserted into the lateral part of the ala of the nose.

*It dilates the anterior nasal apertures as in deep inspiration. It also expresses the anger (sign of omega).*

### Depressor septi

It arises from the incisive fossa of the maxilla and is inserted into the lower mobile part of the nasal septum.

*It fixes the nasal septum to allow dilatation of anterior nasal aperture by dilator naris.*

### **Muscles around the mouth**

The muscles around the mouth are responsible for the movement of lips and cheek. These include:

1. **Orbicularis oris** , which acts as sphincter of oral orifice
2. **Nine muscles** which radiate outwards from the lips like the spokes of a wheel act as dilators of oral orifice.

### **Orbicularis oris (Fig. 3.10 )**

This complex muscle surrounds the oral orifice and forms the greater part of the lips. It has extrinsic and intrinsic portions. The major ***extrinsic (or superficial) portion*** is composed of interlacing fibres of the muscles which converge around the mouth for their insertion into the lips, namely levator anguli oris, depressor anguli oris, buccinator, etc. Most of the fibres come from buccinator. The fibres of buccinator converge towards the modiolus. At modiolus, they form chiasma. The uppermost and lowermost fibres pass straight into their respective lips, whereas the middle fibres decussate, so that the upper fibres pass into the lower lip, and lower into the upper lip.

**FIG. 3.10 ■** Orbicularis oris muscle: ( **A** ) arrangement of fibres and ( **B** ) formation of modiolus.

The ***intrinsic portion*** consists of fibres running obliquely between the skin and mucous membrane of the lips, and incisive slips, which pass laterally into the lips from the jaws adjacent to the incisor teeth and interlace with the fibres of peripheral part of orbicularis oris as they approach the modiolus.

### Nerve supply

Buccal branch of the facial nerve.

### Actions

Because of its complex nature, orbicularis oris is capable of producing wide variety of movements of lips such as closing, pouting, pursing, and twisting.

### CLINICAL CORRELATION

**Paralysis of orbicularis oris:** The paralysis of one-half of orbicularis oris

prevents proper closure of lips on that side. Consequently, the speech is slurred and the saliva escapes between the lips at the angle of the mouth (*dribbling of saliva from the angle of the mouth* ).

### Nine muscles which radiate outward from angle of the mouth

These are as follows:

1. Levator labii superioris alaeque nasi
2. Levator labii superioris
3. Levator anguli oris
4. Zygomaticus minor
5. Zygomaticus major
6. Depressor labii inferioris
7. Depressor anguli oris
8. Risorius
9. Buccinator.

Some authorities says that they are actually converging towards the angle of mouth.

The muscle of chin called *mentalis* is usually discussed with muscles around the mouth.

- **Levator labii superioris alaeque nasi** arises from the frontal process of the maxilla and is inserted into the ala of nose by one slip and to the upper lip by another slip.
  - *It elevates the upper lip and helps to dilate the nostril.*
- **Levator labii superioris** arises from maxilla just above the infraorbital foramen and is inserted into the upper lip.
  - *It elevates the upper lip.*
- **Levator anguli oris** arises from maxilla below the infraorbital foramen and is inserted into the angle of the mouth. It lies deep to levator labii superioris.
  - *It raises the angle of the mouth.*
- **Zygomaticus minor** arises from zygomatic bone and is inserted into the upper lip.
  - *It elevates the upper lip.*
- **Zygomaticus major** arises from zygomatic bone and is inserted into the angle of the mouth.
  - *It draws the angle of the mouth upward and laterally.*

- **Depressor labii inferioris** arises from the anterior oblique line of the mandible and is inserted into the lower lip.  
*◦It draws the lower lip downwards and somewhat laterally.*
- **Depressor anguli oris** arises from the posterior part of the oblique line of the mandible and is inserted into the angle of the mouth.  
*◦It draws the angle of the mouth downwards and laterally.*
- **Risorius** arises from parotid fascia as a continuation of posterior fibres of platysma and is inserted into the angle of the mouth.  
*◦It retracts the angle of the mouth gently.*
- **Mentalis** , a small conical muscle arises from the incisive fossa of the mandible and is inserted into the skin of the lower lip.  
*◦It puckers the chin and protrudes the lower lip.*
- **Buccinator (Bugler's muscle/trumpeter's muscle )** is muscle of the cheek and is discussed in detail in the following text.

### **Buccinator muscle (Fig. 3.11 )**

**Origin:** The buccinator arises from the following four sites:

1. Outer surface of the alveolar process of maxilla opposite three molar teeth.
2. **Fibrous band** that extends from pterygoid hamulus to maxillary tuberosity (pterygomaxillary raphe).
3. **Pterygomandibular raphe** , which extends from pterygoid hamulus to the mandible behind the third molar tooth.
4. Outer surface of the alveolar process of mandible opposite three molar teeth.

After origin, the fibres run towards the mouth and fill the gap between the upper and lower jaws. The fibres are arranged into upper, intermediate, and lower groups.

**Insertion:** The buccinator is inserted in a complicated manner into the upper and lower lips. On reaching near the angle of the mouth:

- (a) Upper fibres pass into upper lip
- (b) Lower fibres pass into the lower lip
- (c) Intermediate fibres decussate and as a result upper fibres of this group pass into lower lip and lower fibres pass into the upper lip.

**Nerve supply:** Buccal branches of facial nerve.

**Actions:**

1. It flattens the cheek against the gum and teeth, and thus prevents the accumulation of food in the vestibule of mouth during

mastication.

2. It is responsible for blowing the cheek and expelling the air between the lips from inflated vestibule as in blowing the trumpet (hence the name *trumpeter's muscle* ).
3. It puts the bolus of food between upper and lower teeth for mastication.

**FIG. 3.11** ■ Buccinator muscle: ( A ) origin and ( B )

location in the face and insertion.

### N.B.

The outer surface of buccinator muscle is covered by *buccopharyngeal* fascia and its inner surface is lined by a mucous membrane. It is pierced by parotid duct. The pterygomandibular raphe separates it from superior constrictor of the pharynx. A gap between maxillary fibres and those from pterygomaxillary raphe provides passage to the tendon of tensor palati. It is the most important accessory muscles of mastication.

### CLINICAL CORRELATION

- **Paralysis of buccinator muscle:** *If the buccinator muscle is paralysed*, as it occurs in facial palsy, the food accumulates in the vestibule of mouth during mastication and the person cannot blow his or her cheek.
- **Modiolus:** It is a dense, compact, mobile, fibromuscular mass situated about 1.25 cm lateral to the angle of the mouth. It is formed because of interlacing of fibres of five muscles which converge towards radiate the angle of the mouth. These muscles of (modioli) are levator anguli oris, zygomaticus major, buccinator, depressor anguli oris, and risorius ([Fig. 3.10 B](#)). It is important for maintaining facial symmetry.

It can be easily palpated by using opposed thumb and index finger to compress the skin and mucosa simultaneously. The pulsations of facial artery can be felt just lateral to the modiolus.

The inadvertent damage of modiolus during plastic surgery leads to unacceptable facial asymmetry.

### Facial muscles and emotional expressions

The facial muscles responsible for important emotional expressions are presented in [Table 3.3](#).

### Clinical testing of the muscles of facial expression in facial palsy AN 43.5

The muscles of facial expression are involved in facial nerve lesion. They are tested clinically in the following ways:

- **Frontalis** , by asking the patient to look upwards without moving his or her head and then look for horizontal wrinkles on the forehead.
- **Corrugator supercilii** , by asking the patient to frown and then look for vertical wrinkles between the two eyebrows.
- **Orbicularis oculi** , by asking the patient to close the eyes tightly.
- **Orbicularis oris** , by asking the patient to whistle.
- **Dilators of the mouth** , by asking the patient to show his or her teeth.
- **Buccinator** , by asking the patient to puff his or her mouth and then blow out the air forcefully.
- **Zygomaticus major** , by asking the patient to laugh.
- **Risorius** , by asking the patient to smile gently.

## Nerve supply of face

### Motor nerve supply of face (Fig. 3.12 )

The motor nerve supply of the face is derived from the **facial nerve** . After coming out of cranial cavity through stylomastoid foramen, the facial nerve wind around the lateral aspect of styloid process and then enters the parotid gland. Here it divides into five terminal branches (namely, **temporal, zygomatic, buccal, marginal mandibular, and cervical** ), which emerge in the face radiating through the anterior border of the parotid gland and supply the muscles of facial expression (Table 3.4 ). These five sets of terminal branches form the **goose-foot pattern** (pes anserinus) on the face (also see page 113). The facial nerve is described in detail in Chapter 22 .

**FIG. 3.12 ■** Motor supply of the muscles of facial expression. Auricular muscles are not shown because they have no role in the facial expression in human beings. CF, cervicofacial trunk; MP, mastoid process; TF, temporofacial trunk.

### TABLE 3.4

#### Innervation of muscles of facial expression by the terminal branches of facial nerve

Terminal branches of facial nerve	Muscles innervated
Temporal branch	<ul style="list-style-type: none"> <li>• Upper part of the orbicularis oculi</li> <li>• Frontalis</li> <li>• Corrugator supercilii</li> </ul>

Zygomatic branch	Lower part of the orbicularis oculi
Buccal branches (a) Upper buccal branch	<ul style="list-style-type: none"> <li>• Zygomaticus major and minor</li> <li>• Levator anguli oris</li> <li>• Levator labii superioris</li> <li>• Levator labii superioris alaeque nasi</li> <li>• Muscles of the nose</li> </ul>
(b) Lower buccal branch	<ul style="list-style-type: none"> <li>• Buccinator</li> <li>• Orbicularis oris</li> </ul>
Marginal mandibular branch	<ul style="list-style-type: none"> <li>• Risorius</li> <li>• Depressor anguli oris</li> <li>• Depressor labii inferioris</li> <li>• Mentalis</li> </ul>
Cervical branch	Platysma

The five branches of facial nerve can be easily remembered by *mnemonic* given below.

**T**en **Z**ebras **B**ugged **M**y **C**ar.

T = Temporal, Z = Zygomatic, B = Buccal, M = Mandibular, C = Cervical

### **N.B.**

The general course of five terminal branches of facial nerve can be easily remembered by putting the palm of your hand over the auricle and spreading the five digits ([Fig. 3.13](#)). The five digits represent the five terminal branches of the facial nerve.

**FIG. 3.13** ■ Lateral view of the face illustrating the simple method of remembering the terminal branches of the facial nerve.

### **CLINICAL CORRELATION AN 28.7**

**Bell's palsy ( Fig. 3.14 ) AN 28.7 :** It is the simplest form of lower motor neuron (LMN) type paralysis of facial muscles due to compression of facial nerve in the facial canal near stylomastoid foramen. The exact aetiology is not known but it is probably due to viral infection.

#### **Characteristic features on the side of paralysis ( Fig. 3.14 )**

1. *Facial asymmetry* (affected side is drawn to the healthy side) due to unopposed action of muscles of normal side.
2. *Loss of horizontal wrinkles on forehead* due to paralysis of occipitofrontalis muscle.
3. Widening of palpebral fissure and inability to close the eye due to paralysis of orbicularis oculi.

4. *Tears flow down from the eye (epiphora )* due to paralysis of the lower part of the orbicularis oculi.
5. *Sagging of the angle of the mouth towards the affected side* and inability of the angle of the mouth to move upwards and laterally during laughing due to paralysis of zygomaticus major.
6. *Loss of nasolabial furrow* due to paralysis of levator labii superioris alaeque nasi.
7. *Accumulation of food into the vestibule of the mouth due to paralysis of buccinator muscle .*
8. *Dribbling of saliva from the angle of the mouth due to paralysis of orbicularis oris .*
9. *Loss of resistance on paralysis sides when one presses cheek with inflated vestibule* and air leaks out from between the lips due to paralysis of buccinator muscle.

**FIG. 3.14 ■** Bell's palsy on the right side. Note the facial asymmetry (right side appears to be pulled on the left side).

### **N.B.**

In **upper motor neuron (UMN) type paralysis** of facial muscles due to involvement of the pyramidal tract, the upper part of the face is not affected. This part of face remains normal because lower motor neurons supplying this part of face receive corticonuclear fibres (upper motor neurons) from cerebral cortex of the both sides (bilateral cortical innervation; for detail, see [Chapter 22](#) ).

### **Sensory nerve supply of face AN 28.2**

The **trigeminal nerve** is the sensory nerve of the face because it supplies whole of the face, except skin over the angle of mandible, which is supplied by great auricular nerve derived from ventral rami of the 2nd and 3rd cervical nerves (C2, C3).

The upper one-third face (developing from frontonasal process) is supplied by ophthalmic division; middle third of face (developing from maxillary processes) is supplied by maxillary division; and lower third of face (developing from mandibular processes) is supplied by mandibular division of the trigeminal nerve.

The territories of cutaneous innervation of ophthalmic, maxillary, and mandibular nerves are not horizontal, but curved in the posterosuperior direction, indicating the direction of growth of brain and head ([Fig. 3.15](#) ). Thus, the original beard area has been drawn up to the temple and necessarily the neck skin is drawn up to overlap the angle of the mandible. This explains the innervation of face by the 2nd cervical nerve (C2).

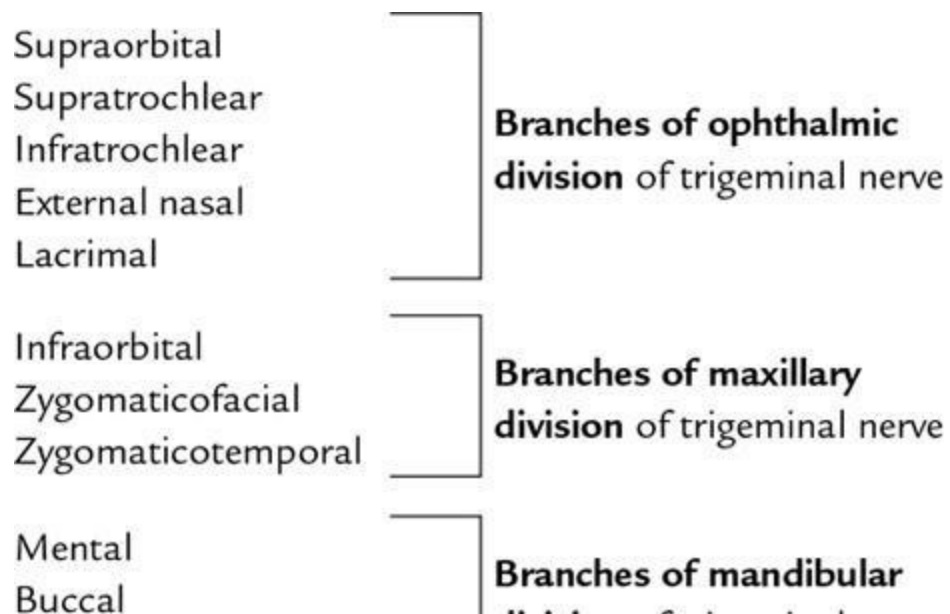

**FIG. 3.15** ■ Sensory innervation of the face. Note trigeminal and spinal fields. V1, ophthalmic division of trigeminal nerve; V2, maxillary division of trigeminal nerve; V3, mandibular division of trigeminal nerve.

The cutaneous nerves of the face derived from three divisions of the trigeminal nerve are given in [Figure 3.16](#) , and summarized as follows:

**FIG. 3.16** ■ Sensory nerves of the face.

Auriculo-temporal

division of trigeminal nerve

## CLINICAL CORRELATION

- **Trigeminal neuralgia (tic douloureux):** It is a clinical condition characterized by sudden paroxysmal attacks of lancinating pain lasting from few hours to several days, confined to distribution of one or more divisions of trigeminal nerve. It commonly starts in the maxillary territory and more frequently on the right side.
- **Herpes zoster ophthalmicus:** It is a viral infection involving the ophthalmic nerve. It presents as severe pain and oedema in the ophthalmic territory and is characterized by the appearance of vesicles along the course of cutaneous branches of the ophthalmic nerve.

### Arterial supply of face AN 28.3

The face is the highly vascular region and is supplied by the following arteries (Fig. 3.17):

1. Facial artery
2. Transverse facial artery
3. Arteries that accompany the cutaneous nerves.

**FIG. 3.17 ■** Arterial supply of the face. 1, zygomaticotemporal; 2, zygomaticofacial; 3, infraorbital; 4, palpebral branch of lacrimal artery.

The main arterial supply to the face is by the *facial artery* ; hence, it is called **chief artery of the face** .

### **Facial artery AN 28.3**

#### **Origin, course, termination, and branches**

It arises from external carotid artery in the neck at the level of greater cornu of the hyoid bone, and after a looped course in the submandibular region, it enters the face by winding around the lower border of the mandible at the anteroinferior angle of the masseter by piercing the investing layer of deep cervical fascia.

In the face, the artery passes tortuously, first upwards and forwards to a point 1.25 cm lateral to the angle of the mouth and then ascends along the side of the nose to the medial angle of the eye where it ends by anastomosing

with the *dorsal nasal branch of ophthalmic artery* . The terminal part of facial artery is called **angular artery** .

The course and branches of facial artery in the neck are described in [Chapter 16](#) .

### Branches of the facial artery in the face

In the face, it gives three sets of named branches, namely:

1. **Inferior labial artery** , to supply the lower lip.
2. **Superior labial artery** , to supply the upper lip.
3. **Lateral nasal artery** , to supply the ala and dorsum of the nose. All these branches arise anteriorly.
4. **Muscular branches** are small, unnamed, and arise from the posterior aspect of the artery.

### N.B.

- The *tortuosity of facial* artery prevents its walls from being unduly stretched during the movements of mandible, lips, and cheeks.
- The facial artery takes part in the formation of numerous anastomoses, namely:
  - Across the midline with the branches of the opposite side. In the lips, the anastomoses between the superior and inferior labial arteries of two sides are large and so efficient that if cut blood spurts from both cut ends.
  - At the medial angle of eye, it anastomoses with the branches of ophthalmic artery, a branch of internal carotid artery and hence the site of anastomosis between the branches of external and internal carotid arteries.

### CLINICAL CORRELATION

- **Wounds of face bleed profusely:** Because the face is richly vascular, the wounds of face bleed profusely but fortunately they heal quickly.
- **Pulsations of facial artery:** They can be felt at two sites, namely:
  - ⌘(a) At the base of the mandible, close to anteroinferior angle of the masseter.
  - ⌘(b) About 1.25 cm lateral to the angle of the mouth.

## Transverse facial artery

It is a small artery that arises from superficial temporal artery, within the parotid gland. After emerging from parotid gland, it runs forwards on the masseter between the zygomatic arch and the parotid duct accompanied by buccal branch of the facial nerve.

## Arteries accompanying the cutaneous nerves

They are small and usually go unnoticed but some of them can be easily seen, that is, infraorbital artery, buccal artery, and mental artery. Note, they all are derived from maxillary artery.

## Venous drainage of face AN 28.3

The venous blood from the face is drained by two veins ([Fig. 3.18](#) ), namely:

1. Facial vein
2. Retromandibular vein.

**FIG. 3.18** ■ Venous drainage of the face.

## Facial vein AN 28.3

### Formation, course, termination, and tributaries

It is the largest vein of the face. It is formed at the medial angle of the eye by the union of supratrochlear and supraorbital veins. After formation, it runs straight downwards and backwards behind the facial artery to reach the anteroinferior angle of the masseter. Here, it pierces the deep fascia, crosses superficial to submandibular gland, and joins the anterior division of *retromandibular vein* below the angle of the mandible to form the *common facial vein*, which drains into the internal jugular vein.

The **tributaries** of facial vein correspond to the branches of facial artery.

### Deep connections AN 28.8

The facial vein communicates with the cavernous sinus through the following two routes:

1. **At the point of commencement**, the facial vein communicates with the superior ophthalmic vein, which passes backwards within the orbit and drains into cavernous sinus.
2. **In the cheek**, the facial vein is joined to the pterygoid venous plexus by the ***deep facial vein***. The deep facial vein passes backwards over the buccinator deep to the ramus of the mandible and communicates with the *pterygoid venous plexus* around the lateral pterygoid muscle, which in turn communicates with the cavernous sinus through an emissary vein.

### Retromandibular vein

The retromandibular vein is formed by the union of the superficial temporal and the maxillary vein within the parotid gland. On leaving the parotid gland, it divides into two divisions: anterior and posterior. The anterior division joins the facial vein to form the common facial vein, whereas posterior division joins the posterior auricular vein to form the external jugular vein.

### CLINICAL CORRELATION

**Dangerous area of the face (Fig. 3.19)**: The facial vein and its communications are devoid of valves in their lumens. Because facial vein rests directly on the muscles of facial expression, movements of these muscles may facilitate the spread of septic emboli from infected area of the

lower part of the nose, upper lip, and adjoining part of the cheek in retrograde direction through **deep facial vein** , pterygoid venous plexus, and emissary vein into the cavernous sinus leading to meningitis and cavernous sinus thrombosis. For this reason, this portion of the face is called *dangerous area of the face* .

**FIG. 3.19** ■ Dangerous area of the face.

### **N.B.**

Infection from dangerous area of face reaches the cavernous sinus mainly through **deep facial vein**.

### **Lymphatic drainage (Fig. 3.20 )**

The face is divided into three lymphatic territories, namely:

1. **Upper territory** comprising greater part of the forehead, later halves of the eyelids including conjunctiva, parotid area, and adjoining part of

the cheek.

◦ *Lymph from upper territory is drained into **preauricular lymph nodes** (also called **superficial parotid lymph nodes**).*

2. **Middle territory** comprising central part of the forehead, medial halves of the eyelids, external nose, upper lip, lateral part of lower lip, medial part of cheek, and greater part of the lower jaw.

◦ *Lymph from middle territory is drained into **submandibular lymph nodes**.*

3. **Lower territory** comprising central part of the lower lip and chin.

◦ *Lymph from lower territory is drained into **submental lymph nodes**.*

**FIG. 3.20 ■** Lymphatic drainage of the scalp and face.

## Eyelids

The eyelids, also called *palpebrae*, are movable curtains in front of the eyeball. They protect the eye from injury, foreign bodies, and bright light. They also keep the cornea moist and clean. The space between the two eyelids is called *palpebral fissure*. The lateral angle of the palpebral fissure where two eyelids meet is called *lateral canthus* of the eye and medial angle of the palpebral fissure where two eyelids meet is called *medial canthus* of the eye.

The free margin of each eyelid is divided into two parts: (1) *Lateral five-sixth ciliary part*, which is flat and possesses eyelashes and (2) *medial one-sixth lacrimal part*, which is round and does not possess cilia (Fig. 3.21).

**FIG. 3.21 ■** Free margins of the eyelids.

## Structure

Each eyelid consists of five layers (Fig. 3.22). From superficial to deep these are as follows:

1. Skin
2. Superficial fascia
3. Orbicularis oculi (palpebral fibres)
4. Tarsal plate and palpebral fascia
5. Conjunctiva.

### Skin

- The skin of eyelids is very thin and without hair except at the lid margin. At the lid margin, it becomes continuous with the

conjunctiva.

### **Superficial fascia**

- The superficial fascia of eyelids is thin, loose, and devoid of fat. It allows the skin to move freely over the lid, and can become greatly swollen with fluid or blood after injury.

### **Orbicularis oculi**

- The fibres of **palpebral part of orbicularis oculi** sweep across the eyelids parallel to the palpebral fissure. A layer of loose areolar tissue lies deep to these fibres, and in the upper eyelid, it is continuous with the subaponeurotic space of the scalp.

### **Tarsal plate and palpebral fascia (Fig. 3.23 )**

- The tarsi are two thin plates of condensed fibrous tissue, which form the *skeleton of the eyelids* and provide them stiffness. The inferior tarsal plate is a narrow strip attached to the inferior orbital margin by palpebral fascia. The superior tarsal plate is much larger and diamond shaped and can be felt if the upper lid is pinched sideways between finger and thumb.
- The medial ends of tarsi are attached to lacrimal crest of maxilla in front of lacrimal sac by a strong fibrous band called **medial palpebral ligament** and lateral ends of tarsi to a tubercle of zygomatic bone (Whitnall's tubercle) by **lateral palpebral ligament** .
- The large modified sebaceous glands (**Meibomian or tarsal glands** ) are partly embedded on the deeper aspects of the tarsal plates. These glands are arranged in a single row and their ducts open into the lid margin by minute foramina behind the eyelashes.
- The **tarsal glands** secrete oily fluid that reduces evaporation of tears and prevent them from overflowing onto the cheek.
- The **ciliary glands** are arranged in several rows immediately behind the root of eyelashes. Their ducts open on the lid margin close to the lashes.
- The ciliary glands are of two types: (a) **glands of Zeis** , which are modified sebaceous glands and open into the follicles of eyelashes, and (b) **glands of Moll** , which are modified sweat glands. They also open into the follicles of the eyelashes.
- The palpebral fascia of upper eyelid is attached above to the superior orbital margin and below to the anterior surface of the

tarsal plate some distance away from its upper border.

- The **palpebral fascia** is the thin fibrous membrane, which connects the tarsi to the orbital margins and forms the **orbital septum** with them. Medially it passes posterior to the lacrimal sac and attached to the posterior margin of the lacrimal groove, which lodges the lacrimal sac.
- The upper palpebral fascia in the upper lid is pierced by:
  1. Fibres of levator palpebrae superioris
  2. Palpebral part of lacrimal gland
  3. Nerves and vessels that pass from orbit to the face.

### **Conjunctiva (palpebral part)**

- It is a transparent mucous membrane, which lines the inner surface of each eyelid. About 2 mm from the edge of each eyelid the palpebral conjunctiva presents a groove where foreign bodies frequently lodge.

**FIG. 3.22 ■** Structure of the eyelid (sagittal section of upper eyelid).

**FIG. 3.23** ■ Tarsal plates and palpebral fascia.

## CLINICAL CORRELATION

- **Ptosis:** It is the drooping of the upper eyelid due to paralysis of levator palpebrae superioris following lesion of oculomotor nerve, which supplies this muscle.
- **Stye (hordeolum):** It is the suppurative inflammation of the Zeis gland. In this condition, the gland is swollen, hard, and painful. The pus points near the base of the cilia, hence can be easily drained by plucking the cilia.
- **Chalazion:** It is the inflammation of the tarsal (Meibomian gland). It causes localized swelling on the inner aspect of the eyelid.
- **Blepharitis:** It is the inflammation of the eyelids mostly involving lid margins.

## Arterial supply

The arterial supply is by medial palpebral branches of ophthalmic artery and lateral palpebral branches of lacrimal artery. These branches form an arterial arch in each eyelid.

## Venous drainage

The venous blood from eyelids is drained into ophthalmic and facial veins.

## Lymphatic drainage

The lymph from medial halves of lid is drained into submandibular lymph nodes and from lateral halves into the preauricular lymph nodes.

### Palpebral fissure

When the eye is open, the eyelids are separated by an elliptical fissure called **palpebral fissure** .

Features seen through palpebral fissure (**Fig. 3.24** )

1. **Lacus lacrimalis**, a small triangular space in the medial part with reddish fleshy looking elevation in its centre called **lacrimal caruncle** .
2. **Plica semilunaris** , a small curved fold of conjunctiva immediately lateral to lacrimal caruncle. It represents nictitating membrane of lower animals.
3. **Cornea and pupil** , present in its centre. Note that upper one-seventh of the cornea is overlapped by the upper eyelid.
4. **Sclera of eyeball** , seen as white areas on either side of cornea.

**FIG. 3.24** ■ Features of the palpebral fissure.

### Development

Above and below the cornea, the eyelids develop as folds of skin, which come

together and adhere along their edges during the 3rd month of intrauterine life. The space between the folds and the cornea is the **conjunctival sac** .

When the eyelids separate, the palpebral fissure is established.

The orbital septum develops from mesodermal core in the skinfolds. When the eyelids are closed, the orbital septum from orbital margin to the eyelids forms a complete diaphragm of the orbital cavity; the medial part of orbital septum passes behind the lacrimal sac and is attached to the lacrimal bone. This attachment produces sharp **posterior lacrimal crest** .

## CLINICAL CORRELATION

- **Surgical operations on the lacrimal sac** , therefore, are always anterior (outside) to the orbital cavity proper because orbital septum passes behind the lacrimal sac to gain attachment on the posterior lacrimal crest.
- The condensation and thickening of orbital septum within the developing eyelids form the tarsal plates.

## Conjunctiva

The conjunctiva is a thin transparent mucous membrane, which lines the inner surfaces of eyelids (*palpebral conjunctiva* ) and the front of sclera and cornea of eyeball (*bulbar conjunctiva* ). The potential space between eyelids and eyeball when eyes are closed is called **conjunctival sac** . The lines of reflexion between palpebral and bulbar conjunctiva above and below form the **superior** and **inferior fornices** , respectively.

The palpebral conjunctiva is highly vascular and firmly adherent to the tarsal plates. On the contrary, bulbar conjunctiva is loose over the sclera but firmly adherent to the cornea forming its anterior epithelium (the corneal epithelium). The conjunctiva contains mucus-secreting goblet cells.

## Conjunctival fluid

The conjunctival sac is filled with three films of fluid; from within outwards these are as follows:

1. Watery from lacrimal fluids
2. Mucus from conjunctiva
3. Oily from tarsal glands.

The blinking movements of eyelids make these films moisten cornea and help drain the conjunctival fluid into nasal cavity.

## CLINICAL CORRELATION

- The inflammation of conjunctiva (*conjunctivitis*) due to infection or allergy is one of the commonest diseases of the eye. *Trachoma* is a granular conjunctivitis caused by bacterium *Chlamydia trachomatis*. It is contagious and considered as the commonest cause of blindness in India.
- It is usual for physician to examine palpebral conjunctiva for *anaemia* and bulbar conjunctiva for *jaundice*.

### Nerve supply

The conjunctiva is supplied by the following nerves:

1. Palpebral conjunctiva of upper eyelid and ocular conjunctiva by ophthalmic nerve
2. Palpebral conjunctiva of lower eyelid by maxillary nerve.

### Arterial supply

The conjunctiva is supplied by palpebral and anterior ciliary arteries derived from ophthalmic artery.

### Venous drainage

The venous blood from palpebral conjunctiva is drained into facial vein while from ocular conjunctiva into ophthalmic veins.

### Lymph drainage

The lymph from conjunctiva is drained into preauricular lymph nodes.

## Lacrimal apparatus AN 31.4

The structures concerned with secretion and drainage of lacrimal (tear) fluid, together form the ***lacrimal apparatus*** (Fig. 3.25). AN 31.4

**FIG. 3.25 ■** Lacrimal apparatus.

## Components

The lacrimal apparatus consists of the following structures:

1. Lacrimal gland and its ducts
2. Conjunctival sac
3. Lacrimal puncta
4. Lacrimal canaliculi
5. Lacrimal sac
6. Nasolacrimal duct.

## Lacrimal gland and its ducts

The lacrimal gland is a (J-shaped) *serous gland*. It consists of upper large **orbital part** and lower small *palpebral part*. The two parts are continuous with each other around the lateral margin of the levator palpebrae superioris.

The *orbital part* is almond shaped and situated in the lacrimal fossa in the anterolateral part of the roof of the bony orbit.

The *palpebral part* is one-third of the size of the orbital part and is situated in the lateral part of the upper eyelid below the levator palpebrae superioris and extends up to the superior fornix of conjunctiva.

## N.B.

*Accessory lacrimal glands (glands of Krause):* These are very small serous glands located beneath the palpebral conjunctiva near the fornices. They are about 35–40 in the upper eyelid and 6–8 in the lower eyelid.

The *ducts of lacrimal gland* are approximately 12 in number, about 4 or 5 from orbital part and 6–8 from palpebral part. The ducts of orbital part of gland passes through palpebral part of gland. They open into the lateral parts of the superior fornix of the conjunctival sac.

Lacrimal gland secretes the ***lacrimal (tear) fluid*** and its ducts convey it to conjunctival sac.

About 1 mL of lacrimal fluid is secreted per day. Half of it evaporates and remaining half is drained into lacrimal sac.

### *Functions of lacrimal fluid*

1. Flushes the conjunctiva and keeps the cornea moist.
2. Provides nourishment to cornea.
3. Serves to express emotions – shedding of tears during grief and sorrow.
4. Prevents infection (for it contains bactericidal lysozyme).

## CLINICAL CORRELATION

When lacrimal gland fails to secrete lacrimal fluid as in case of Bell's palsy, the **artificial tears** are instilled in the eye at regular intervals to prevent the cornea from drying and desiccation.

Ducts from orbital part traverse the palpebral part to open into conjunctival sac. Therefore, removal of palpebral part of gland is functionally equivalent to removal of the entire lacrimal gland.

The removal of entire lacrimal gland does not lead to dryness of conjunctiva because it is kept moist by the secretions of accessory lacrimal

glands.

### Arterial supply

It is by lacrimal branch of ophthalmic artery.

### Venous drainage

It is by ophthalmic veins.

### Nerve supply of lacrimal gland (Fig. 10.25 )

The lacrimal gland is supplied by parasympathetic, sympathetic, and sensory fibres through lacrimal nerves. The following nerves supply the lacrimal gland:

**1. Parasympathetic (secretomotor) supply** of the lacrimal gland:

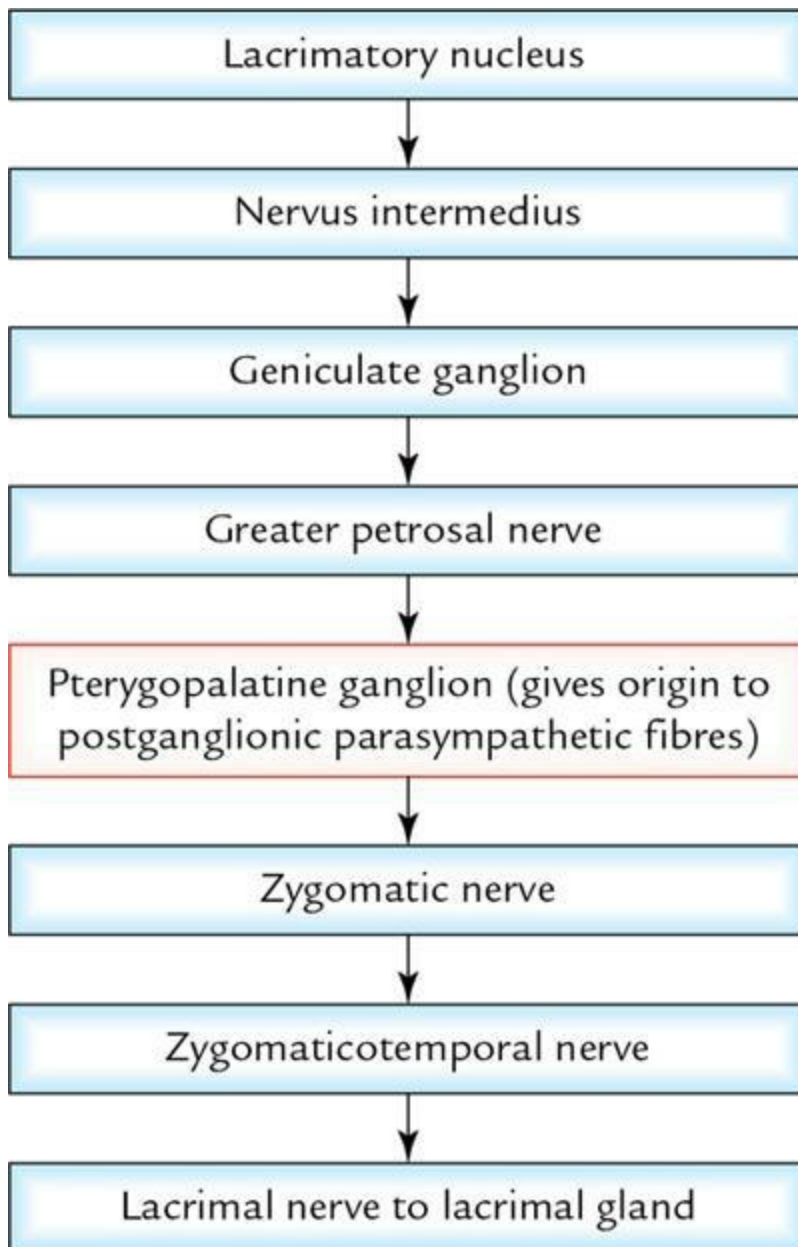

The pathway of parasympathetic innervation is as follows:

- (a) The *preganglionic parasympathetic fibres* arise from lacrimal nucleus in the pons and pass successively through nervus intermedius, geniculate ganglion, greater petrosal nerve, nerve of pterygoid canal to reach the pterygopalatine ganglion where they relay.
- (b) The *postganglionic fibres* arise from the cells of the pterygopalatine ganglion and pass successively through maxillary nerve, zygomatic nerve, zygomaticotemporal nerve, and lacrimal nerve to reach the lacrimal gland.

*This parasympathetic pathway is summarized in [Flowchart 3.1](#) .*

**2. Sympathetic (vasomotor) supply:** The pathway of sympathetic innervation is as depicted in [Flowchart 3.2](#) .

**3. Sensory supply:** It is by sensory fibres of lacrimal nerve, a branch of ophthalmic division of trigeminal nerve.

**FLOWCHART 3.1 ■** Parasympathetic pathway of lacrimal gland.

**FLOWCHART 3.2** ■ Sympathetic pathway of lacrimal gland.

### **Conjunctival sac**

It is a potential space between palpebral and bulbar conjunctiva.

### **Lacrimal puncta**

These are minute openings on the summits of lacrimal papillae on the lid margins.

At the junction of lateral 5/6th and medial 1/5th of lid margin, there is a small conical projection called **lacrimal papilla** surmounted by a tiny aperture called **lacrimal punctum**. The lacrimal papilla faces inwards towards the **lacus lacrimalis**.

## Lacrimal canaliculi

There are two lacrimal canaliculi, superior and inferior in upper and lower eyelids, respectively. Each canaliculus measures about 10 mm in length and begins at lacrimal punctum. The superior canaliculus at first runs upwards and then bends downwards and medially along the free margin of the eyelid to open into the lacrimal sac.

The *inferior canaliculus* at first runs downwards and then bends upwards and medially, to open into the lacrimal sac. At the bending, each canaliculus presents a small dilatation called *ampulla*.

### N.B.

- Both canaliculi converge medially towards the lacrimal sac into which they open separately but sometimes by a common dilated stem.
- Canaliculi lie behind the medial palpebral ligament.
- Canaliculi are lined by stratified squamous epithelium and contain elastic fibres in their walls, which make them dilatable by the probe.
- A few muscle fibres derived from lacrimal part of orbicularis oculi are arranged circularly around the base of the lacrimal papilla and exert sphincteric action.

## Lacrimal sac

It is the upper dilated end of the nasolacrimal duct. It is situated in the deep lacrimal groove bound by posterior lacrimal crest of lacrimal bone and anterior lacrimal crest of frontal process of the maxilla. The sac is enclosed in the lacrimal fascia; when distended, the lacrimal sac is about 15 mm long and 5–6 mm in breadth. It is divisible into three parts: fundus, body, and neck from above downwards. The narrow neck becomes continuous with nasolacrimal duct.

### **Relations** (Fig. 3.26):

- *Anteriorly*: Medial palpebral ligament
- *Posteriorly*: Lacrimal part of orbicularis oculi (which arises from crest of lacrimal bone and from lacrimal fascia)
- *Laterally*: Lacrimal fascia, which is derived from orbital periosteum and minute plexus of veins
- *Medially*: Lacrimal groove and minute arterial plexus.

**FIG. 3.26 ■** Relations of the lacrimal sac.

### Nasolacrimal duct

It is a membranous canal, about 18 mm long, extending from neck of lacrimal sac to the anterior part of inferior meatus of the nose. It is lodged in the bony canal formed by maxilla, lacrimal bone, and inferior nasal concha. Its lower opening presents an incomplete mucous fold called *lacrimal fold* **or** *valve of Hasner*, which prevents the air from blowing the duct into the eye when one blasts his or her nose to clean nasal secretions.

### Factors helping the drainage of tears

Drainage of tears occurs by the following means:

1. Blinking movements of eyelids
2. Capillary action of the film of the fluid
3. Contraction of lacrimal part of orbicularis oculi leading to distension of lacrimal sac.

### Development of nasolacrimal duct and lacrimal sac

The nasolacrimal duct develops from a solid cellular **ectodermal cord**, which forms along the nasolacrimal groove, the line of fusion of maxillary and lateral nasal processes. Later, the cord becomes submerged beneath the surface ectoderm and becomes canalized during the 3rd month to form the

nasolacrimal duct. The upper end of the duct widens to form the lacrimal sac, which develops secondary connection with the conjunctival sac by lacrimal canaliculi.

## CLINICAL CORRELATION

**Epiphora:** It is an overflow of tears from conjunctival sac over the cheeks. It may occur because of:

- Excessive secretion of tears (*hyperlacrimation*) following intake of spicy food or emotional outbreak, or
- Obstruction in lacrimal passages, namely, lacrimal punctum, lacrimal canaliculi, lacrimal sac, and nasolacrimal duct or
- Eversion of lower eyelid (*ectropion*), hence that of lacrimal papilla and lacrimal punctum due to laxity of orbicularis oculi in old age or loss of its tone due to paralysis.

## Golden Facts to Remember

• <b>Most obvious feature of the scalp</b>	Galea aponeurotica (epicranial aponeurosis)
• <b>Richest cutaneous blood supply in the body</b>	In the region of scalp
• <b>Most important layer of the scalp from clinical point of view</b>	Fourth layer (i.e., layer of loose areolar tissue)
• <b>Dangerous layer of the scalp</b>	Layer of loose areolar tissue (fourth layer)
• <b>Most common form of birth trauma of the scalp</b>	Caput succedaneum
• <b>Toughest fascia in the body</b>	Temporal fascia
• <b>Sensory supply of whole face is by trigeminal nerve except</b>	Skin over the angle of the mandible which is supplied by great auricular nerves (C2, C3)
• <b>Chief artery of the face</b>	Facial artery
• <b>Largest vein of the face</b>	Facial vein
• <b>Muscle of the body with longest name</b>	Levator labii superioris alaeque nasi

• <b>Most important accessory muscle of mastication</b>	Buccinator
---	------------

## CLINICAL CASE STUDY

### Case I

A 55-year-old school teacher went to his family physician and complained that since morning he has not been able to close his right eye, and during eating, the food accumulates between the teeth and cheek on the right side. He is also not able to whistle or puff out his cheek properly.

On examination, the physician made the following observations:

- The right side of face appeared flattened and expressionless.
- Loss of wrinkles on the forehead on the right side.
- Saliva drooled out from the right corner of the mouth.
- When patient smiled, the lower portion of right half of the face was pulled to the left side and right corner of the face was not raised.

Based on above observations, the physician concluded that all the muscles of facial expression on the right side of teacher's face are paralysed and he diagnosed him as a case of **Bell's palsy**.

### Questions

1. What are the characteristic features of muscles of facial expression?
2. What is Bell's palsy? Mention its most common cause.
3. What is the difference between upper and lower motor neuron type of facial palsies?

### Answers

1. They are located in the superficial fascia and inserted into the skin of the face. All of them are supplied by the facial nerve.
2. It is lower motor neuron (LMN) type of facial palsy. The exact cause is not known but most probably it occurs because of compression of facial nerve in the facial canal just above the stylomastoid foramen following an inflammation.
3. In lower motor neuron facial palsy, whole of the face on the side of lesion is paralysed, whereas in upper motor neuron facial palsy, the

upper part of face is not affected and only lower half of the face on the opposite side is paralysed.

## Case II

An 18-year-old girl was suffering from **acne vulgaris** in the mask area of her face. After few weeks, the acne got infected and converted into pustules. She scratched pustules which spilled pus. After few weeks, she felt sharp severe headache, swelling and bulging of the eyes and surrounding tissues, high temperature, and double vision. She went to an ophthalmologist who after thorough examination diagnosed her as a case of **cavernous sinus thrombosis**.

## Questions

1. How does the infection from mask area of her face reached the cavernous sinus?
2. What are the nerves present in the cavernous sinus?
3. What is location of cavernous sinus?

## Answers

1. Through deep facial vein, pterygoid venous plexus an emissary vein into cavernous sinus.
2. Third nerve, fourth cranial nerve, and ophthalmic and mandibular divisions of fifth cranial nerve.
3. Within cranial cavity, one on other side of pituitary fossa.

---

# Chapter 4: Skin, superficial fascia and deep fascia of the neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the parts, extent, attachments, and modifications of deep cervical fascia. **AN 35.1**
- Describe the fascial spaces of neck. **AN 35.10**
- Describe external jugular vein in brief. **AN 43.5**
- Draw the labelled diagrams to show horizontal and vertical dispositions of deep cervical fascia.
- Write short notes on: (a) dermatomes of head and neck, (b) platysma, (c) superficial cervical lymph nodes, (d) carotid sheath, and (e) pretracheal fascia.
- Give the anatomical basis of: (a) air embolism following external jugular vein cut about 1 inch (2.5 cm) above clavicle, (b) thyroid gland moves up and down during swallowing, and (c) external jugular vein is used by clinicians to measure pressure in right atrium.

The knowledge of skin, superficial fascia, and deep fascia of the neck is extremely important. The lines of cleavage in skin help to plan the direction of **surgical incisions**. The structures within superficial fascia help in closing the surgical incisions and stop profuse bleeding. The deep fascia forms fascial compartments and spaces in the neck. It also forms fascial planes along which infection can travel from one place to the other. The superficial veins in the neck are often examined to assess the state of health.

The external jugular vein is often seen on the side of neck especially in thin individuals. The raised jugular venous pressure is suggestive of **congestive**

**cardiac failure .**

## Skin

The skin in the region of neck is thin and normally under tension. The direction of tension lines (also called *cleavage lines* or *Langer's lines* ) often corresponds with the wrinkle lines. The cleavage (*Langer's* ) lines are disposed transversely around the neck. Therefore, surgical incisions made along these lines, that is, transverse incisions, in neck heal with invisible scars.

### Cutaneous innervation

The cutaneous innervation of the neck is derived from C2, C3, and C4 spinal segments.

**FIG. 4.1 ■** Dermatomes of the head and neck.

The 1st cervical (C1) nerve has no cutaneous branch and ventral rami of C5–T1 form the brachial plexus to supply the upper limb.

The skin above the C2 dermatome is supplied by trigeminal nerve and the skin below the C4 dermatome is supplied by T2 spinal segment ([Fig. 4.1](#) ).

The skin on the anterolateral aspect of the neck is supplied by four

cutaneous nerves derived from cervical plexus formed by ventral rami of C2, C3, and C4 spinal nerves (page 84).

The skin on the posterior aspect of the neck is supplied by dorsal rami of C2, C3, and C4 spinal nerves.

## Superficial fascia

The superficial fascia of the neck consists of a thin layer of loose areolar tissue and contains a thin sheet of muscle called **platysma** .

In addition to platysma, it also contains cutaneous nerves, superficial veins, superficial lymph nodes, and lymph vessels.

*The cutaneous nerves and veins lie deep to the platysma .*

The amount of subcutaneous fat in neck region is more in children and women than in men.

### **Platysma (Fig. 4.2 )**

It is a thin quadrilateral broad sheet of muscle in the superficial fascia of the side of the neck. It ascends onto the face from the front of the neck.

Morphologically, it represents the remnant of **panniculus carnosus** of animals. It develops from the 2nd pharyngeal arch. It covers the anteroinferior part of the posterior triangle and superior part of the anterior triangle of the neck.

**FIG. 4.2 ■** Origin and insertion of the platysma.

### Origin

The platysma arises from skin and deep fascia covering the upper parts of the pectoralis major and anterior part of the deltoid muscle.

### Insertion

After origin, the fibres sweep upwards and forwards superficial to the clavicle and sternocleidomastoid. It crosses over the lower part of the posterior triangle and upper part of the anterior triangle to reach the lower border of the mandible, where anterior fibres decussate with the corresponding fibres of the opposite side across the midline for about 2.5 cm below and behind the symphysis menti (Fig. 4.3 ).

**FIG. 4.3 ■** Decussation of the anterior fibres of platysma. Also note the location of anterior jugular veins and jugular venous arch.

Most of the fibres (intermediate and posterior) are inserted into the lower border of the body of the mandible. Some posterior fibres pass superficial to the angle of the mandible and masseter muscle and then turn medially to insert into the skin of angle of the mouth through *risorius* (Fig. 4.2 ).

### Nerve supply

The platysma is supplied by the cervical branch of the facial nerve.

### Actions

1. **Acting from above** , the platysma produces vertical ridges in skin of the neck releasing the pressure of skin over the underlying veins and thus helps in the venous return. It, therefore, serves to ease the pressure of tight collar.
  - These ridges are often seen in long distance racers and old age persons.

2. **Acting from below** , it helps to depress the mandible and draws the angle of the mouth downwards and laterally as in expression of terror/horror.

### **N.B.**

Though risorius appears to be a continuation of platysma, it has a different nerve supply, namely, the buccal branch of facial nerve.

### **CLINICAL CORRELATION**

**Suturing of skin incisions of neck:** The surgeons while closing an incision in the neck, suture platysma meticulously as a separate layer to prevent adhesion of skin and subcutaneous tissue to deeper neck muscles because such adhesions cause the overlying skin to move as the deeper muscles contract or relax and the wound will heal with an ugly scar, which is cosmetically unacceptable.

Because superficial veins of the neck lie under the cover of platysma, the retraction of divided platysma keeps the cut veins open. These veins are unable to retract because of their attachment to the deep cervical fascia. However, if deep fascia is cut, the veins retract and most of the bleeding stops.

### **Cutaneous nerves of the neck**

**Skin on back of the neck** is supplied segmentally by cutaneous nerves, derived from dorsal rami of C2, C3, and C4 spinal nerves ([Fig. 4.4](#) ). Cutaneous nerves of back of neck are described in [Chapter 7](#) .

**FIG. 4.4 ■** Cutaneous nerves of the neck.

The **skin on the front and side of the neck** on each side is supplied by four cutaneous nerves derived from ventral rami of C2–C4 spinal nerves through branches of the cervical plexus (Fig. 4.4 ).

They are named as follows:

1. Lesser occipital nerve (C2)
2. Great auricular nerve (C2 and C3)
3. Transverse cervical nerve (C2 and C3)
4. Supraclavicular nerves (C3 and C4).

The course and distribution of these nerves are described in [Chapter 5](#) .

### **Superficial veins of the neck (Fig. 4.5 )**

There are two superficial veins of the neck. These are as follows:

1. External jugular vein
2. Anterior jugular vein.

**FIG. 4.5 ■** Superficial veins of the neck.

### **External jugular vein (Fig. 4.5 ) AN 43.5**

It begins just below the angle of the mandible by the union of posterior division of retromandibular vein and posterior auricular vein. It then runs vertically downward and laterally across the sternocleidomastoid under the cover of platysma to pierce the deep cervical fascia in the anteroinferior angle of the posterior triangle about 2.5 cm above the clavicle along the posterior border of the sternocleidomastoid and enters the supraclavicular space. After passing through this space, it terminates in the subclavian vein. The external jugular vein varies considerably in its size and course. It becomes visible in

old age particularly when the individual holds his or her breath or blows his or her cheek with mouth closed, as it impedes the venous return to the right side of the heart and distends the vein.

### Surface anatomy

The external jugular vein can be marked on the surface by a line extending downward and backward from angle of the mandible to the middle of the clavicle.

Its **tributaries** (Fig. 4.5 ) are as follows:

1. Posterior auricular vein	Formative tributaries
2. Retromandibular vein	
3. Posterior external jugular vein	
4. Oblique jugular vein	
5. Transverse cervical vein	Terminal tributaries
6. Suprascapular vein	
7. Anterior jugular vein	

### N.B.

The **posterior auricular vein** descends behind the auricle to join the posterior division of retromandibular vein. **Posterior external jugular vein** descends along the posterior border of sternocleidomastoid to join the external jugular vein a little below the midpoint of posterior border of the muscle. The oblique jugular vein communicates with the internal jugular vein in the upper part of the neck. The suprascapular, transverse cervical, and anterior jugular veins join the external jugular vein in the posterior triangle.

There are two pairs of valves in the lumen of the external jugular vein, one at its site of termination into the subclavian vein and the other about 4 cm above the clavicle. These valves, however, do not prevent regurgitation of blood.

### CLINICAL CORRELATION

- **Venous air embolism:** The wall of the external jugular vein is adherent to deep fascia where it pierces the investing layer of deep cervical fascia (about 2.5 cm above the clavicle). Therefore, if external jugular vein is cut at this site, its walls cannot collapse. Consequently, air is sucked into

its lumen because of negative intrathoracic pressure during inspiration leading to **venous air embolism** which may cause death subsequently.

- **Central venous cannulation:** The external jugular vein is occasionally used for **central venous cannulation** , but because of its variable size and presence of valves, it is often difficult to manipulate the cannula through the lower part of the vein. The right external jugular vein being in the most direct line with the superior vena cava, is the one most commonly used.
- **Jugular venous pressure:** The external jugular vein is often examined by clinicians to assess the **venous pressure** in the right atrium. Normally, in recumbent (lying down) position, the lower one-third of the vein becomes filled with blood but it collapses on reclining at 45 degrees angle. However, if it remains full even when the patient reclines at 45 degrees angle, it suggests increased right atrial pressure often seen in congestive cardiac failure.

### **Anterior jugular vein (Fig. 4.5 )**

It begins below the chin in the submental region by the union of small unnamed veins from the chin. It descends in the superficial fascia about 1 cm lateral to the midline.

At about 2.5 cm above the suprasternal notch, it pierces the investing layer of deep cervical fascia to enter the **suprasternal space (of Burns)** , where it turns sharply laterally and passes deep to sternocleidomastoid and terminates in the external jugular vein. In the suprasternal space, the anterior jugular vein is united across the midline to its fellow of opposite side by a transverse venous channel called **jugular venous arch** .

### **Superficial cervical lymph nodes and lymph vessels**

The **superficial cervical lymph nodes** (Fig. 4.6 ) are situated near the surface of neck, mostly around the junction of the head with the neck. They drain all the superficial structures and some deep structures of the head. Most of the efferent lymph vessels from these lymph nodes pass to deep cervical lymph nodes arranged along the internal jugular vein. A few scattered superficial nodes are found along the external and anterior jugular veins. They also drain into deep cervical lymph nodes.

**FIG. 4.6 ■** Superficial cervical lymph nodes.

The superficial cervical lymph nodes situated around the junction of head and neck form *pericervical/cervical collar* . They are arranged into the following groups:

1. Submental nodes
2. Submandibular nodes
3. Superficial parotid (preauricular) nodes
4. Retroauricular (mastoid) nodes
5. Occipital nodes.

### **Submental nodes**

Three or four in number, the **submental nodes** lie on mylohyoid muscle below the symphysis menti (chin) and receive the lymph from the tip of the tongue, lower lip, and chin.

### **Submandibular nodes**

The submandibular nodes, about half a dozen in number, lie on the surface of the submandibular gland and receive the lymph from the face, cheek, nose, upper lip, gums, and tongue.

### **Superficial parotid (preauricular) nodes**

The preauricular nodes lie superficial to parotid fascia and drain the lymph

from the scalp, auricle, eyelids, and cheeks.

### **Retroauricular/mastoid (postauricular) nodes**

One or two in number, the retroauricular nodes lie on the mastoid process and drain the lymph from the scalp and auricle.

### **Occipital nodes**

One or two in number, the occipital nodes lie on trapezius about 2.5 cm inferolateral to theinion and drain the lymph from the scalp. They are notable for being palpable in **German measles** .

These groups form a kind of ring of lymph nodes at the junction of the head and neck, and may appropriately be called **necklace of lymph nodes at the craniocervical junction** (Fig. 4.7 ). The lymph nodes of pericervical collar are clinically palpable only when enlarged.

**FIG. 4.7** ■ Ring of superficial cervical lymph nodes at the junction of the head and neck.

## **Deep cervical fascia (fascia colli) AN 35.1**

The deep cervical fascia of the neck (Figs 4.8 and 4.9 ) is clinically very important because it forms various **fascial spaces** in the neck.

**FIG. 4.8 ■** Vertical extent and disposition of the three layers of the deep cervical fascia. Buccopharyngeal fascia is also shown. Note the continuity of fascial spaces of the neck into the mediastinum.

**FIG. 4.9** ■ Diagrammatic transverse section through neck at the level of the 6th cervical vertebra to show the horizontal disposition of the three layers of deep cervical fascia.

It also provides **capsules to the glands** and **invests the muscles in the region**. In addition, *it forms protective sheaths around neurovascular structures*. The layers of deep cervical fascia form fascial planes to direct the spread of infection or pus in the neck.

## Layers of deep cervical fascia

The deep cervical fascia of the neck consists of three layers. From outside inwards, these are as follows:

1. ***Investing layer of deep cervical fascia***
2. ***Pretracheal fascia***
3. ***Prevertebral fascia***.

The spaces among the structures of the neck are filled with loose areolar tissue. The structures of the neck are mostly destined to move up and down. The layers of deep cervical fascia are no more than the laminar condensation of loose areolar tissue produced by the movements of these structures.

These laminar condensations take different names in different regions and are continuous with each other either directly or indirectly through loose areolar tissue.

The loose areolar tissue forms fascial sheets or laminae in the same way as unwoven cotton forms sheets of cloth after spinning.

These laminae ensheath muscles and other moving structures. This permits movement between the sheaths and movements of structures within them.

### **Investing layer of deep cervical fascia**

This layer encircles the neck like a collar, deep to platysma and superficial fascia.

When traced horizontally, it encloses the sternocleidomastoid and trapezius – the two large superficial muscles on either side of the neck (Fig. 4.9 ).

#### *Attachments*

1. **Superiorly** , it is attached to external occipital protuberance, superior nuchal line, mastoid process, and lower border of mandible from behind forwards.
2. **Inferiorly** , it is attached to the spine of scapula, acromion process, upper aspect of clavicle, and jugular notch of manubrium sterni from behind forwards.
3. **Anteriorly** , across the midline, it becomes continuous with its counterpart of the other side. In the anterior midline, it is attached to symphysis menti, hyoid bone jugular notch from above downwards.
4. **Posteriorly** , it is attached to ligamentum nuchae and spine of 7th cervical vertebra.

### **Tracing of the investing layer**

#### **• Horizontal tracing**

◦When traced forwards from its attachment to ligament nuchae, it first splits to enclose the trapezius, then forms the roof of the posterior triangle, then again splits to enclose the sternocleidomastoid and finally forms the roof of the anterior triangle.

#### **• Vertical tracing**

◦When traced upwards above the hyoid bone, it splits to enclose the

submandibular salivary gland (Fig. 4.10 ). The superficial layer covers the superficial surface of the gland and it is attached to the lower border of the body of the mandible. The deep layer covers the medial surface of the gland and is attached to the mylohyoid line of the mandible.

Posterior to the submandibular gland, at the lower pole of the parotid gland, it splits to enclose this gland also (Fig. 4.10 B).

**FIG. 4.10 ■** Investing layer of the deep cervical fascia enclosing two glands: ( A ) parotid gland and ( B ) submandibular gland.

The superficial layer is strong and covers the superficial surface of the parotid gland as **parotidomasseteric fascia** to get attached to the lower border of the zygomatic arch. The deeper layer passes deep to the parotid gland to get attached to the lower border of the tympanic plate and styloid process of the temporal bone. The part of this layer stretching between the styloid process and the angle of mandible condenses to form the **stylomandibular ligament** which separates the parotid gland from submandibular gland.

*When traced downwards* , the fascia splits twice to enclose two spaces suprasternal and supraclavicular.

- *Above the suprasternal notch* , it splits into two layers to enclose **suprasternal space (of Burns)** before being attached to the anterior and posterior borders of the suprasternal notch.

The **suprasternal space** contains (Fig. 4.11 A):

- (a) Sternal heads of sternocleidomastoid muscles
- (b) Jugular venous arch
- (c) Interclavicular ligament
- (d) Lymph node (sometimes).

◦ *Above the middle third of clavicle*, it splits into two layers to enclose the **supraclavicular space** (Fig. 4.11 B). The anterior and posterior layers get attached to the anterior and posterior borders of the upper surface of the clavicle. The posterior layer encloses the inferior belly of omohyoid and after being attached to clavicle, it becomes continuous with the posterior layer of **clavipectoral fascia**.

**FIG. 4.11 ■ ( A ) Suprasternal space (of Burns) and ( B ) Investing layer of the deep cervical fascia enclosing supraclavicular space.**

The **supraclavicular space** contains ([Fig. 4.11 B](#)):

- (a) Terminal part of the external jugular vein
- (b) Supraclavicular nerves before they become cutaneous.

The investing layer also forms fascial pulleys to anchor the tendons of the digastric and omohyoid muscles.

### **N. B.**

**‘Rule of 2’**. When summed up, it is noted that investing layer of deep cervical fascia presents everything in ‘2’, for examples:

- It **encloses 2 muscles**, trapezius and sternocleidomastoid.
- It **forms roofs of 2 triangles**, anterior and posterior triangles.
- It **splits to enclose 2 glands**, submandibular and parotid.
- It **splits to enclose 2 spaces**, suprasternal and supraclavicular.
- It **forms 2 fascial slings (pulleys)** for inferior belly of omohyoid and intermediate tendon of digastric muscle.

Hence, investing layer of deep cervical fascia is called as **layer of two’s**.

### **Pretracheal fascia**

This layer of deep cervical fascia covers the front and sides of trachea, hence its name *pretracheal fascia*. It splits to enclose the thyroid gland forming its capsule and is attached to the oblique line of thyroid cartilage and to the arch of cricoid cartilage anteriorly. A fibrous band called **ligament of Berry** is derived from this fascia and connects the capsule of the lateral lobe of the thyroid gland to the cricoid cartilage ([Fig. 4.12](#)).

**FIG. 4.12** ■ Vertical disposition of pretracheal fascia enclosing thyroid gland.

## Tracing of the pretracheal fascia

### • **Horizontal tracing**

- When traced horizontally, it merges with the investing layer of deep cervical fascia enclosing the sternocleidomastoid and the anterior wall of the carotid sheath (Fig. 4.9).

### • **Vertical tracing**

- When traced above, it encloses thyroid gland lying in front of trachea which in turn lies in front of oesophagus. Then it extends up where it is attached to the hyoid bone.
- When traced below the thyroid gland, it enters the thorax in front of the trachea and blends with the apex of the fibrous pericardium.

## CLINICAL CORRELATION

- The attachment of pretracheal fascia to hyoid bone and thyroid and cricoid cartilages allows the **thyroid gland to move up and down with the larynx during swallowing** .
- The layers of pretracheal fascia which cover the posterior surface of the thyroid lobe is ill defined. As a result, enlarged thyroid (goitre) easily bulges posteriorly to compress the oesophagus causing dysphagia.
- The pretracheal fascia provides a slippery surface to allow free movements of trachea during swallowing.

### Prevertebral fascia

It is extremely strong and lies in front of the prevertebral muscles.

### Tracing of the prevertebral fascia

- **Horizontal tracing** (Fig. 4.9 )
  - When traced laterally, it covers the scalene muscles, levator scapulae, and splenius capitis forming the fascial carpet of the posterior triangle. The ventral rami of cervical spinal nerves that form the cervical and brachial plexuses lie deep to it (Fig. 4.9 ).

As the trunks of brachial plexus and subclavian artery emerge between the scalenus anterior and scalenus medius and move towards the axilla, they carry with them a tubular sheath of this fascia, called **axillary sheath** , which may extend up to the elbow.

### N.B.

The subclavian and axillary veins lie outside the sheath to allow their free dilation during increased venous return from the upper limb.

- **Vertical tracing** ( Fig. 4.8 )
  - *Traced above* , the fascia extends up to the base of the skull to which it is attached.
  - *Traced below* , it continues downwards in front of longus colli muscles into the superior mediastinum where it blends with the anterior longitudinal ligament of the upper thoracic vertebrae (T1–T3).

## Other features

- **Retropharyngeal space** Anteriorly, the prevertebral layer of deep cervical fascia is separated from posterior aspect of the pharynx and its covering, buccopharyngeal fascia, by a potential space called **retropharyngeal space** (Figs 4.8 and 4.13 ). On either side of this space lies carotid sheath. This space allows the expansion of the pharynx during swallowing. The retropharyngeal space is visible only when distended with fluid or pus. The retropharyngeal space is continuous with the parapharyngeal spaces at the sides of the pharynx. The retropharyngeal space is divided into two lateral compartments (**spaces of Gillette** ) by a midline fibrous raphe. Each lateral space contains retropharyngeal lymph nodes.
- **Danger space of neck** . It lies behind the retropharyngeal space, extending from base of skull to the posterior mediastinum. It contains small amount of loose fatty connective tissue. It is bounded anteriorly by alar fascia and posteriorly by prevertebral fascia. It provides the potential path for spread of infection from pharynx (retropharyngeal abscess) to the mediastinum.
- **Prevertebral space:** The space behind the prevertebral fascia and in front of the vertebral bodies is called **prevertebral space** . It extends from base of skull to the coccyx.

**FIG. 4.13** ■ Retropharyngeal space.

## CLINICAL CORRELATION

- The *infections of retropharyngeal space* can pass down behind the oesophagus and may extend into the posterior mediastinum, of course, through superior mediastinum.
- The *retropharyngeal abscess* due to involvement of retropharyngeal lymph nodes produces paramedian unilateral bulge in the posterior pharyngeal wall due to fusion of buccopharyngeal fascia to the prevertebral fascia in the median plane.
- *Tubercular caries of cervical vertebrae* produces abscess in the prevertebral space which often extends into the retropharyngeal space.
- *Pus collected in the prevertebral space* because of caries of cervical vertebrae may travel forward and cause midline bulge in the posterior pharyngeal wall. Pus may travel laterally first into the posterior triangle deep to fascial carpet formed by prevertebral fascia and then along the axillary sheath into the axilla or even into the arm.

### Other derivatives of the deep cervical fascia

These include:

1. Carotid sheath
2. Buccopharyngeal fascia
3. Pharyngobasilar fascia.
4. Alar fascia.

### Carotid sheath

It is a tubular condensation of deep cervical fascia around the: (1) common carotid and internal carotid arteries, (2) internal jugular vein, and (3) vagus nerve ([Fig. 4.14](#)). The vagus nerve lies posteriorly between the vein and arteries. The carotid sheath is wedged between the three layers of the deep cervical fascia, that is, investing layer, pretracheal fascia, and prevertebral fascia, and attached to all these layers by loose areolar tissue. The sheath is thick around common and internal carotid arteries but thin over the internal jugular vein in order to allow its expansion during increased venous return.

**FIG. 4.14 ■ Carotid sheath: ( A ) surface view and ( B ) sectional view.**

Carotid sheath extends from the base of the skull above to the arch of aorta below. At the base of the skull, it is attached to the margins of the carotid canal and jugular fossa. At the arch of aorta, it blends with its tunica adventitia.

## Relations

1. The ansa cervicalis is embedded in the anterior wall of the carotid sheath.
2. The cervical sympathetic chain is closely related to posterior wall of the sheath, plastered to the prevertebral fascia.

## N.B.

In addition to structures mentioned above, the carotid sheath also contains:

- a) Some deep cervical lymph nodes
- b) Carotid sinus nerve
- c) Sympathetic nerve fibres (carotid periarterial plexuses)
- d) 9th, 11th, and 12th cranial nerves in the upper part only.

## CLINICAL CORRELATION

The malignant and tuberculous deep cervical lymph nodes frequently become adherent to the internal jugular vein. Therefore, during *block dissection of the neck*, the sheath is exposed and a portion of the vessel is resected to facilitate removal of these lymph nodes.

## **Buccopharyngeal fascia**

It is a delicate and distensible layer of fascia that covers the constrictor muscles of pharynx and buccinator muscle. The buccopharyngeal fascia extends from the base of the skull to the oesophagus.

## **Pharyngobasilar fascia**

It is formed by thickening of submucosa of pharyngeal wall, hence lies between mucosa and constrictors of pharynx. Superiorly it anchors superior constrictor muscle to the skull base ([Fig. 14.7](#) , 201).

## **Alar fascia**

It is an independent coronal fascial layer which extends between the carotid sheath of two sides ([Fig. 4.9](#) ). Vertically it extends from base of skull to body of C7 vertebra below ([Fig. 4.8](#) ). When it is fused with buccopharyngeal fascia anteriorly.

## **Modification of deep cervical fascia AN 35.1**

They have already been described. However, for the sake of convenience, they are summarized as follows:

1. Investing layer of deep cervical fascia
2. Pretracheal fascia
3. Prevertebral fascia
4. Carotid sheath
5. Buccopharyngeal fascia
6. Pharyngobasilar fascia.

## **Fascial spaces (or tissue spaces) of neck AN 35.10**

These are potential spaces which exist between the fascia and underlying organs/tissues. They are filled with loose areolar tissues. They are common sites for collection of pus and fluids.

## **Classification**

### *A. In relation to parotid region*

- **Parotid space** is located between parotid fascia and parotid gland.

### *B. In relation to mandible*

- **Submental space** is located under chin between mylohyoid

superiorly and platysma inferiorly.

- **Sublingual space** is located below the tongue and above the mylohyoid muscle.
- **Submandibular space** is located on superficial surface of mylohyoid muscle, between anterior and posterior bellies of digastric muscle.
- **Submasseteric space** is located between masseter and lateral aspect of ramus of mandible.
- **Pterygomandibular space** is located between medial side of ramus of mandible and lateral surface of medial pterygoid muscle.
- **Buccal space** is located superficial to buccinator muscle and deep to platysma muscle and the skin.

*C. In relation to pharynx*

- **Retropharyngeal space** is located between posterior aspect of pharynx and prevertebral layer of deep cervical fascia.
- **Danger space** is located behind retropharyngeal space.
- **Parapharyngeal space** is located on the side of pharynx between its lateral wall and mandible.

*D. In relation to neurovascular structures*

- **Carotid space** is located deep to carotid sheath and structures surrounded by it. It is located on the side of neck.

*E. In relation to vertebral column*

- **Prevertebral space** is located between prevertebral layer of deep cervical fascia and vertebral column.

*F. In relation to larynx and trachea*

- **Thyroid space** is located between thyroid gland and pretracheal layer of deep cervical fascia.

## Golden Facts to Remember

• <b>Most important superficial vein in the neck</b>	External jugular vein
• <b>Most commonly used external jugular vein for central venous cannulation/catheterization</b>	Right external jugular vein
• <b>Muscle of the neck representing panniculus carnosus of lower animals</b>	Platysma
• <b>Cold abscess (tubercular abscess)</b>	Abscess without signs of

	acute inflammation like pain and redness
• <b>Commonest cause of cold abscess in the neck</b>	Tuberculosis of cervical vertebrae (caries of cervical vertebrae)
• <b>Ligament of Berry</b>	Fibrous band connecting thyroid capsule to the cricoid cartilage
• <b>Muscle in the neck, which serves to ease the tight collar</b>	Platysma

## CLINICAL CASE STUDY

A 27-year-old individual reported to the emergency OPD. He had linear cut on the anterolateral aspect of his neck which was bleeding profusely. On examination, the doctors found that the wound was superficial and not involving any major structure that could threaten his life. The wound was located in the upper part of the carotid triangle. He was diagnosed as a case of **‘superficial wound of neck’**.

It was cleaned and stitched. The individual was discharged and given a course of antibiotics. He was asked to come for removal of stitches after 7 days. After removal of stitches, a wide ugly scar was seen on the side of the cut.

## Questions

1. Enumerate the structures present in the superficial fascia of the neck (anterolateral aspect).
2. Why do superficial cut wounds in the region of neck bleed profusely?
3. What likely mistake the doctor could have made during stitching that resulted in wide ugly scar?

## Answers

1. Platysma, superficial veins, cutaneous nerves, superficial lymph nodes, and lymph vessels.
2. The superficial cut wounds of the neck bleed profusely because retraction of divided platysma keeps the cut superficial veins open.
3. The doctor may not have sutured the platysma as a separate layer; for details, refer to Clinical Correlation on page 69.

---

# Chapter 5: Side of the neck, sternocleidomastoid muscle and posterior triangle

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the posterior triangle of neck under following headings: (a) location and boundaries, (b) contents, and (c) applied anatomy.
- Enumerate: (a) structures piercing roof of posterior triangle, (b) cutaneous nerves of cervical plexus, and (c) nerves emerging on the side of neck at the nerve point of neck.
- Describe the sternocleidomastoid muscle under the following headings: origin, insertion, relations, nerve supply and actions. **AN 29.1**
- Give the anatomical basis of: (a) torticollis, (b) cold abscess in posterior triangle, (c) cervical plexus nerve block, and (d) subclavian artery pulse.
- Describe anatomical basis of torticollis/wry neck. **AN 29.3**

The side of the neck is roughly **quadrangular in shape**. It is bounded *anteriorly* by anterior midline of the neck, *posteriorly* by anterior border of the trapezius, *superiorly* by the lower border of the body of the mandible and a line extending from the angle of the mandible to the mastoid process, and *inferiorly* by the clavicle.

The side of the neck is divided into anterior and posterior triangles.

The side of the neck is the common site for various pathological lesions, such as, lymphadenopathy, cysts, tumours. It is also a frequent site for performing various clinical procedures, such as, biopsy, venepuncture, nerve block.

## Surface Landmarks on the Side of the Neck (Fig. 5.1 )

1. **Sternocleidomastoid** forms the most important landmark on the side of the neck. It becomes prominent when the face is turned to the opposite side and is seen as a raised ridge extending obliquely from the sternum to the mastoid process.
2. **Mastoid process** is a large bony projection easily felt behind the lower part of the auricle.
3. **Anterior border of trapezius** becomes prominent when shoulder is elevated against the resistance.
4. **Lesser supraclavicular fossa** is a small triangular depression above the medial end of the clavicle between the sternal and clavicular heads of sternocleidomastoid. It overlies the internal jugular vein.
5. **Greater supraclavicular fossa** is a depression above the middle one-third of the clavicle. It overlies the cervical part of brachial plexus and the third part of the subclavian artery.
6. **Transverse process of first cervical vertebra** can be felt on deep pressure midway between the angle of the mandible and mastoid process. It is crossed by spinal accessory nerve.
7. **Lower border of the mandible** can be easily felt by running a finger backwards from chin to the angle of the mandible.
8. **Clavicle** being subcutaneous can be palpated along its entire extent at the junction of the neck and chest.

**FIG. 5.1 ■** Surface landmarks on the side of the neck.

### **Skin, Superficial Fascia, and Deep Fascia**

The skin, superficial fascia, and deep fascia on the side of neck are described in [Chapter 4](#) .

### **Superficial Muscles of the Neck**

The two large superficial muscles of the neck are **sternocleidomastoid** and **trapezius** .

### **Triangles on the Side of the Neck**

The side of the neck is quadrangular in shape (vide supra).

This quadrilateral area is divided into large anterior and posterior triangles by the sternocleidomastoid muscle which runs across this area diagonally from mastoid process above to the upper end of the sternum and adjoining part of clavicle below. ([Fig. 5.2](#) ).

**FIG. 5.2 ■** Boundaries and triangles on the side of the neck. The quadrilateral shape of the side of the neck with posterior and anterior triangles can be well appreciated by the figure in the inset.

This chapter deals with sternocleidomastoid muscle and posterior triangle. The anterior triangle is described in [Chapter 6](#) .

The students should first know the attachments of two major superficial muscles, that is, sternocleidomastoid and trapezius, encountered on the side of neck before studying anterior and posterior triangles, both these muscles are supplied by the spinal accessory nerve. The **trapezius muscle** acting mainly on shoulder girdle is described in [Chapter 7](#) on page 98; sternocleidomastoid is described in the following text.

### **Sternocleidomastoid muscle (Fig. 5.3 ) AN 29.1**

This is the key muscle of the neck which extends obliquely across the side of the neck, dividing it into posterior and anterior triangles.

**FIG. 5.3 ■** Origin and insertion of the sternocleidomastoid muscle.

## Origin

The muscle arises by two heads: sternal and clavicular.

1. **Sternal head** is tendinous and arises by a rounded tendon from the superolateral part of the front of the manubrium sterni, below the suprasternal notch and passes upwards, backwards, and laterally in front of the sternoclavicular joint.
2. **Clavicular head** is flat and musculoaponeurotic. It arises from the

medial third of the superior surface of the clavicle. It passes vertically upwards deep to the sternal head with which it unites to form a fusiform belly.

### **N.B.**

A small triangular gap exists between the two heads above the sternoclavicular joint. It is called **lesser supraclavicular fossa** . It contains the terminal part of the internal jugular vein, which can be entered at this site by a needle or catheter.

### **Insertion**

The muscle is inserted by: (1) a thick tendon on the lateral surface of the mastoid process extending from its tip to its base and (2) a thin aponeurosis into the lateral half of the superior nuchal line of the occipital bone.

*Mnemonic* : The attachments of sternocleidomastoid are remembered by its name itself: sterno = from sternum, cleido = clavicle, and from mastoid = mastoid process.

### **Arterial supply**

The sternocleidomastoid muscle is supplied by four sternocleidomastoid branches of following arteries:

1. **Upper part** , by occipital and posterior auricular arteries.
2. **Middle part** , by superior thyroid artery.
3. **Lower part** , by suprascapular artery.

### **N.B.**

The knowledge of arterial supply is important to make muscle flap in reconstructive surgery.

### **Nerve supply**

The sternocleidomastoid muscle is supplied by the **spinal accessory nerve** . It is also supplied by the ventral rami of **C2 and C3** , which are mostly sensory and carry proprioceptive sensations from the muscle.

### **Actions**

When muscle contracts, it tilts the head towards the shoulder on the same side and rotates the head so that face turns to the opposite side ([Fig. 5.4 A](#)).

This movement occurs during an upward sideways glance.

**FIG. 5.4** ■ Actions of the sternocleidomastoid muscle. ( **A** ) Ipsilateral flexion and contralateral rotation when acting alone. ( **B** ) Flexion of head, when acting together.

When muscles of both sides contract together they draw the head forwards as in lifting the head from the pillow or bending the head during eating food (Fig. 5.4 B).

### Relations

The two-headed sternocleidomastoid muscle is enclosed in the investing layer of deep cervical fascia. It is pierced by the spinal accessory nerve and four sternomastoid arteries. Its superficial and deep relations are as follows.

### Superficial relations

- Skin
- Superficial fascia
- Platysma
- Two cutaneous nerves

(a) Great auricular	
---------------------	--

(b) Transverse cervical

crosses from posterior to anterior side

- External jugular vein, crosses obliquely from above downwards and laterally
- Superficial cervical lymph nodes
- Superficial lamina of investing layer of deep cervical fascia
- Parotid gland

## Deep relations

- **In the upper part**
  - (a) *Muscles*: Posterior belly of digastric, longissimus capitis, and splenius capitis
  - (b) *Artery*: Occipital artery
- **In the middle part**
  - (a) *Muscles*: Levator scapulae, scalenus anterior, scalenus medius, scalenus posterior, splenius capitis, inferior belly of omohyoid
  - (b) *Arteries*: Common carotid, internal carotid
  - (c) *Veins* : Internal jugular, anterior jugular
  - (d) *Nerves*: Vagus, spinal accessory, cervical plexus, brachial plexus (upper part), ansa cervicalis (inferior root)
  - (e) *Glands*: Thyroid gland, lymph nodes
- **In the lower part**
  - (a) *Muscles*: Sternohyoid, sternothyroid, scalenus anterior
  - (b) *Arteries*: Suprascapular, transverse cervical
  - (c) *Veins*: Anterior jugular
  - (d) *Nerves*: Brachial plexus (lower part), phrenic nerve
- Deep cervical lymph nodes.

## CLINICAL CORRELATION AN 29.3

### **Torticollis or wry neck (*Latin torticollis* = *twisted neck*; Fig. 5.5**

**)**: It is a clinical condition in which neck is twisted to the side of lesion, i.e., head is bent to the same side and face and chin points to the opposite side and up. This usually occurs due to spasm of sternocleidomastoid muscle supplied by spinal accessory nerve.

- The *spasmodic torticollis* is characterized by painful contraction of the sternocleidomastoid muscle on one side. It is usually caused by

exposure to cold and maladjustment of head with pillow during sleep.

- The *reflex torticollis* occurs due to irritation of spinal accessory nerve caused by inflamed or suppurating lymph nodes.
- The *congenital torticollis* occurs due to birth injury to muscle. Permanent torticollis may occur due to subsequent ischaemic contracture.

**FIG. 5.5 ■ Torticollis/wry neck.**

## Posterior triangle AN 29.1

It is the triangular space on the side of neck behind the sternocleidomastoid muscle. Its apex is directed upwards and backwards towards the mastoid process and base downwards towards the clavicle (Figs 5.6 to 5.8 ).

### Boundaries (Fig. 5.6 A)

#### *Anterior*

- Posterior border of sternocleidomastoid muscle.

#### *Posterior*

- Anterior border of trapezius muscle.

*Inferior (base)*

- Superior aspect of middle third of the clavicle.

*Superior (apex)*

- Meeting point of sternocleidomastoid and trapezius muscles at the superior nuchal line of the occipital bone.

**FIG. 5.6 ■** A Boundaries and floor of the posterior triangle. B Structures piercing the roof of the posterior triangle.

### Floor (Fig. 5.6 A)

The floor of posterior triangle is muscular and is formed from above downwards by the following muscles:

1. Semispinalis capitis (occasionally)
2. Splenius capitis
3. Levator scapulae
4. Scalenus medius
5. Scalenus posterior.

### N. B.

Semispinalis capitis and splenius capitis are described in [Chapter 7](#) and levator scapulae in [Chapter 5](#), vol 1, scalenus medius and scalenus anterior

mucles in [Chapter 12](#) and omohyoid in [Chapter 6](#) .

### Roof ([Fig. 5.6 B](#))

It is formed by the investing layer of the deep cervical fascia, stretching between the sternocleidomastoid and trapezius muscles.

The **superficial fascia overlying the roof** contains platysma, external jugular and posterior jugular veins, and cutaneous nerves and vessels.

**Structures piercing the roof** of the posterior triangle are as follows:

1. Four cutaneous branches of cervical plexus:

- (a) Lesser occipital nerve (C2)
- (b) Great auricular nerve (C2, C3)
- (c) Transverse cervical nerve (C2, C3)
- (d) Supraclavicular nerves (C3, C4).

They pierce the roof near the middle of the posterior border of the sternocleidomastoid muscle (for details see page 83).

2. **External jugular vein** : It begins just below the angle of mandible, and runs downwards and backwards crossing the sternocleidomastoid obliquely and under the cover of platysma (for details see page 70).

### Fascial carpet of the posterior triangle

The muscular floor of posterior triangle is covered by prevertebral layer of deep cervical fascia, which forms the **fascial carpet of the floor of the posterior triangle** . It forms sheath around subclavian artery and brachial plexus travelling from the root of the neck to the upper limb as axillary sheath.

The lower part of the posterior triangle is crossed by inferior belly of omohyoid superficial to the fascial carpet.

### CLINICAL CORRELATION

**Cold abscess in posterior triangle:** Pus collected in the posterior triangle deep to its fascial carpet as pus trickles down from tubercular abscess of cervical vertebrae. It may further trickle downwards and laterally along the axillary sheath to first appear in the axilla or then even in the arm subsequently.

### Subdivisions ([Fig. 5.7](#) )

The posterior triangle is subdivided into two parts by the inferior belly of the

omohyoid, which crosses the lower part of the triangle obliquely upwards and forwards: (1) a larger upper part called **occipital triangle** and (2) a small lower part called **subclavian (supraclavicular) triangle**. These parts are so named because they contain occipital and subclavian arteries, respectively.

**FIG. 5.7** ■ Subdivisions and main contents of the posterior triangle.

### Contents (Figs 5.7 and 5.8 )

#### 1. *In the occipital triangle (i.e., above the omohyoid)*

- (a) Spinal accessory nerve
- (b) 3rd and 4th cervical nerves providing branches to levator scapulae and trapezius muscles

- (c) Dorsal scapular nerve (C5)
- (d) Four cutaneous branches of cervical plexus (initial parts)
- (e) Superficial transverse cervical artery
- (f) Occipital artery.

**2. *In the subclavian/supraclavicular triangle (i.e., below the omohyoid)***

- (a) 3rd part of the subclavian artery
- (b) Subclavian vein
- (c) Terminal part of external jugular vein
- (d) Trunks of brachial plexus
- (e) Superficial (transverse) cervical, suprascapular, and dorsal scapular arteries
- (f) Lymph nodes.

**FIG. 5.8 ■** Schematic diagram showing the floor and contents of the right posterior triangle.

### **N.B.**

The most important contents of posterior triangle are: (1) third part of subclavian artery, (2) brachial plexus (cervical part), (3) spinal accessory nerve, and (4) lymph nodes.

- All the important contents of the posterior triangle lie deep to the fascial carpet of the floor except spinal accessory nerve, which lies just underneath the roof. In operations on the posterior triangle, all the structures except spinal accessory nerve are safe, provided fascial carpet

of posterior triangle is left intact.

## Relevant features of some of the contents

### 1. Spinal accessory nerve:

- This nerve pierces anterior border of sternocleidomastoid muscle about 3 cm from mastoid process through the muscle substance and emerges in the posterior triangle by piercing the posterior border of the sternocleidomastoid (a little above the middle of this border). In this situation, it is related to *cervical lymph nodes* of the upper deep cervical chain ([Fig. 5.9](#)).
- The nerve then crosses the posterior triangle by running downwards and laterally just below the roof of triangle parallel to the fibres of levator scapulae muscle to disappear underneath the anterior border of trapezius (approximately 5–6 cm above the clavicle) and supplies trapezius muscle. In the posterior triangle it is adherent to the deep aspect of the fascial roof of this triangle.

**FIG. 5.9** ■ Course of spinal accessory nerve right through sternocleidomastoid muscle. Note the relation of lymph nodes to this nerve.

### N.B.

More proximally, the spinal accessory nerve lies in front of transverse

process of atlas vertebra runs downwards and laterally to enter anterior border of sternocleidomastoid muscle and supplies it (Fig. 5.9 ).

## CLINICAL CORRELATION

The **spinal accessory nerve** may be damaged in operations involving the removal or biopsy of lymph nodes in the posterior triangle of the neck. This will lead to paralysis of trapezius muscle causing difficulty in combing hair.

### 2. Four cutaneous branches of cervical plexus ( Fig. 5.10 ):

- Although cervical plexus is located deep to the sternocleidomastoid, its cutaneous branches emerge at the midpoint or just above the midpoint of the posterior border of the sternocleidomastoid by piercing the deep cervical fascia.
- The course and distribution of these cutaneous nerves are as follows:
  - (a) The **lesser occipital nerve** hooks around the spinal accessory nerve and ascends for a short distance along the posterior border of sternocleidomastoid to innervate the skin of the upper one-third of the cranial surface of the auricle and that of the head behind the auricle.
  - (b) The **great auricular nerve** runs forward and upward across the sternocleidomastoid towards the angle of mandible where it divides into anterior and posterior branches. It first supplies the skin of the face over the angle of the mandible and then the skin over the mastoid region and lower part of both the surfaces of the auricle.
  - (c) The **transverse cervical nerve** passes forward across the sternocleidomastoid deep to the external jugular vein and then divides into ascending and descending branches to supply the skin of the front of the neck.
  - (d) The **supraclavicular nerve** arises as a common trunk which descends downwards and divides into medial, intermediate, and lateral supraclavicular nerves.
    - (i) The **medial supraclavicular nerve** crosses in front of the medial one-third of the clavicle to supply the skin on the chest up to the 2nd rib.
    - (ii) The **intermediate supraclavicular nerve** passes in front of the middle third of the clavicle to supply the

skin on the front of the chest. Occasionally, it pierces the clavicle through and through.

- (iii) The **lateral supraclavicular nerve** crosses in front of the lateral third of the clavicle and supplies the skin over the shoulder and the upper half of the deltoid muscle.

**FIG. 5.10** ■ Cutaneous branches of the cervical plexus. Note the location of ‘nerve point of the neck’ (*dotted red circle*) .

## CLINICAL CORRELATION

**Nerve point of the neck:** The point at the junction of the upper and middle third of the posterior border of sternocleidomastoid where **four cutaneous nerves of cervical plexus** (namely, *lesser occipital*, *great auricular*, *transverse cervical*, and *supraclavicular*) and **spinal accessory** nerve emerge is termed **nerve point of the neck**.

*Mnemonic: L*et's *G*o *T*o *S*antokh *S*ingh.

In **cervical plexus nerve block** the anaesthetic agent is injected at this site.

### 3. Muscular branches to levator scapulae and trapezius (C3, C4):

- They appear at about the middle of sternocleidomastoid. The branches going to levator scapulae soon end in it, whereas those going to trapezius run below and parallel to the spinal accessory nerve and cross the middle of the triangle.

### 4. Nerve to rhomboids:

- It pierces scalenus medius muscle and immediately passes deep to levator scapulae muscle.

### 5. Cervical part of the brachial plexus:

- The roots and trunks of brachial plexus lie in the neck.

Four branches arise from cervical part of brachial plexus – two from roots and two from trunks ([Fig. 5.11](#)).

- (a) *Dorsal scapular nerve* arises from C5 root. It pierces the scalenus medius and runs laterally across it to pass deep to levator scapulae, which it supplies.
- (b) *Long thoracic nerve (or nerve to serratus anterior)* arises from C5, C6, and C7 roots. It passes downwards behind the brachial plexus and third part of the subclavian artery. It crosses the first rib to supply the serratus anterior muscle.
  - Remember that C5 and C6 roots pierce the scalenus medius and C7 root joins the nerve at the lower level in the axilla.
- (c) *Nerve to subclavius* arises from upper trunk (C5 and C6). It passes downwards in front of brachial plexus and subclavian vessels to supply the subclavius muscle.
- (d) *Suprascapular nerve* also arises from the upper trunk (C5 and C6). It passes laterally deep to inferior belly of omohyoid and trapezius to enter the supraspinous fossa through suprascapular notch to supply

the supraspinatus and infraspinatus muscles.

**6. Transverse cervical artery:**

◦This is a branch of thyrocervical trunk of the first part of subclavian artery. It passes laterally and upwards crossing the scalenus anterior, upper trunk of brachial plexus, and scalenus medius. At the lower border of levator scapulae, it divides into the superficial and deep branches called transverse cervical and dorsal scapular arteries respectively.

**7. Suprascapular artery:**

◦This is also a branch of thyrocervical trunk. It passes laterally and backwards behind the clavicle to reach the upper border of the scapula.

**8. Dorsal scapular artery:**

◦It arises as deep branch of transverse cervical artery, but sometimes it arises from the third part of the subclavian artery. It passes laterally in front of scalenus medius and through the brachial plexus to reach the superior angle of the scapula.

**9. Occipital artery:**

◦It is a branch of external carotid artery. It crosses the apex of the triangle superficial to the semispinalis capitis.

**10. Subclavian artery:**

◦It passes behind the scalenus anterior over the first rib. It is closely related to the **lower trunk of the brachial plexus** .

**11. Subclavian vein:**

◦It passes in front of scalenus anterior over the first rib.

**12. Terminal part of external jugular vein:**

◦It pierces the fascial roof of the posterior triangle approximately 2.5 cm above the clavicle to terminate in the subclavian vein (for details see [Chapter 4](#) , page 70).

**13. Lymph nodes:**

◦These are lymph nodes found at the following sites in the posterior triangle:

(a) *A chain of nodes along the posterior border of sternocleidomastoid .*

(b) *A chain of nodes along the spinal accessory nerve .*

(c) *A few nodes in the apical region of the triangle called occipital lymph nodes .*

(d) *A group of lymph nodes in the supraclavicular part of*

triangle called *supraclavicular lymph nodes* lie superficial to brachial plexus and subclavian vessels.

**FIG. 5.11** ■ Branches arising from cervical part (roots of trunks) of brachial plexus. NS, nerve to subclavius; SS, suprascapular nerve.

### Anterior triangle

Anterior triangle is the triangular space on the side of the neck, in front of the sternocleidomastoid (for details, see [Chapter 6](#), page 87).

### CLINICAL CORRELATION

- **Brachial plexus block:** The brachial plexus in the posterior triangle is located below the line extending from the posterior border of the sternocleidomastoid (at the level of cricoid cartilage) to the midpoint on the superior aspect of the clavicle. In this region, the brachial plexus can be blocked by injection of a local anaesthetic between the first rib and

the skin above the clavicle. The brachial plexus block is sometimes done to perform surgical procedures in the upper limb.

- **Pulsations of subclavian artery** can be felt at the root of the neck by pressing behind the clavicle at the posterior border of the sternocleidomastoid muscle.

The haemorrhage from the arteries of the upper limb can be stopped by pressing subclavian artery on to the first rib lateral to the lower end of the sternocleidomastoid muscle.

- **Swelling in the posterior triangle:** The most common cause of swelling in the posterior triangle is due to enlargement of lymph nodes. The supraclavicular lymph nodes are commonly involved and are enlarged in tuberculosis, Hodgkin disease, and malignant growth of breast, arm, and chest. The left supraclavicular lymph nodes (also called *Virchow's lymph nodes*) are commonly involved in metastasis from cancer of stomach, cancer of testis, and cancer of other abdominal organs. The biopsy of these lymph nodes is helpful in early diagnosis of distant malignancies.

### **Golden Facts to Remember**

• <b>'Key muscle' of the neck</b>	Sternocleidomastoid
• <b>All the important structures of posterior triangle are present deep to prevertebral fascia (fascial carpet),</b>	Spinal accessory nerve which runs underneath the roof
• <b>Most common cause of swelling in the posterior triangle</b>	Enlargement of supraclavicular lymph nodes
• <b>Most commonly injured nerve during removal of enlarged cervical lymph nodes in the posterior triangle</b>	Spinal accessory nerve
• <b>Most important surface landmark on the side of the neck</b>	Sternocleidomastoid
• <b>Virchow's lymph nodes</b>	Left supraclavicular lymph nodes
• <b>Pulsations of subclavian artery can be felt by</b>	Pressing downwards above the clavicle at the posterior border of sternocleidomastoid
• <b>Commonest cause of cervical lymphadenopathy in adults</b>	Metastatic deposits of cancer cells in cervical lymph nodes

## CLINICAL CASE STUDY

A 65-year-old woman visited her family physician with a swelling in her neck in the region of left posterior triangle. The swelling had gradually increased in size. On examination, it felt very hard and the physician thought that it was due to enlarged lymph node/nodes containing secondary carcinoma (cancer). He referred her to the hospital where she underwent fine needle aspiration biopsy followed by open excisional biopsy. Following surgery, the patient complained that she was not able to elevate her left shoulder above 90 degrees to comb her hair. On examination, it was found that her left trapezius was paralysed, whereas left sternocleidomastoid was normal, and the **physician concluded that the spinal accessory nerve might have been excised inadvertently during biopsy**.

### Questions

1. What could be the cause of paralysis of her left trapezius?
2. Describe the course of spinal accessory nerve in the posterior triangle.
3. Why is spinal accessory nerve liable to injury during the excisional biopsy of enlarged cervical lymph nodes in the posterior triangle?
4. Why sternocleidomastoid is not paralysed?

### Answers

1. *Injury to spinal accessory nerve* which provides motor supply to the trapezius.
2. Refer to pages 82–83.
3. Refer to pages 82–83.
4. Because spinal accessory nerve supplies sternocleidomastoid before entering the posterior triangle.

---

# Chapter 6: Anterior region of the neck: Anterior triangle, ansa cervicalis and infrahyoid/strap muscles

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the boundaries and subdivisions of anterior triangle. **AN 32.1**
- Describe the boundaries and contents of submental, digastric/submandibular, carotid and muscular triangles. **AN 32.2**
- Describe the attachments of omohyoid muscle. **AN 29.4**
- Write short notes on: (a) external carotid artery, (b) ansa cervicalis, and (c) infrahyoid muscles.
- Give the anatomical basis of: (a) carotid sinus syndrome, (b) carotid pulse, and (c) why great vessels of neck are not involved in cut throat wounds.

The triangular area on the front of the neck between the two sternocleidomastoid muscles is called *anterior region of the neck*. It is limited above by lower border of the body of mandible and line extending on either side from the angle of the mandible to the mastoid process, and below by the suprasternal notch. This area includes both (right and left) **anterior triangles**, and **suprahyoid** and **infrahyoid areas** ([Fig. 6.1](#)).

**FIG. 6.1 ■** Schematic diagram of anterior median region of the neck showing suprahyoid and infrahyoid area.

The anterior region of the neck is divided by the anterior median line (extending from symphysis menti to the jugular notch) into two anterior triangles of the neck.

Anterior median region of the neck is 2–3 cm wide strip extending from symphysis menti to the suprasternal notch.

Before going into details of anterior triangles of the neck, it is of great clinical importance to know the structures in the anterior median line of the neck. The identification of these structures is essential while performing tracheostomy. It is also useful in clinical examination of midline swellings of the neck.

## Structures in the anterior midline of the neck

Deep to skin and underlying the superficial and deep cervical fasciae, anterior median region (2–3 cm wide) of neck extends from symphysis menti to

suprasternal notch. It presents the following structures in the anterior midline. From above downwards these are ([Fig. 6.2](#)):

1. **Symphysis menti** : Its lower border can be felt where two halves of the body of the mandible unite in the midline.
2. **Fibrous raphe**: It extends from symphysis menti to the hyoid bone. Mylohyoid muscles of both sides meet along this raphe to form the floor of the mouth (diaphragma oris).
3. **Hyoid bone** : It is a horseshoe-shaped bone suspended inferior to mandible by stylohyoid ligaments like children's swing. Hyoid bone does not articulate with any other bone and has only muscular and ligamentous attachments. It lies at the level of C3 vertebra. The regions above and below the hyoid bone are called **suprahyoid region** and **infrahyoid region** , respectively.
4. **Median thyrohyoid ligament** : It is the midline thickening of the thyrohyoid membrane that connects the upper border of thyroid cartilage to the upper border of body of hyoid bone. The membrane is separated from the hyoid bone by a **subhyoid bursa** .
5. **Upper border of the thyroid cartilage** : It is notched and can be felt. It lies opposite the body of C4 vertebra.
6. **Angle of the thyroid cartilage** : It forms the laryngeal prominence, which is more prominent in adult males and is called **Adam's apple** .
7. **Median cricothyroid ligament** : It is the midline thickening of the cricothyroid membrane extending between upper border of cricoid cartilage and lower border of the thyroid cartilage.
8. **Cricoid cartilage** : It lies at the lower border of C6 vertebra and is the **most important surface landmark on the front of the neck** because a number of important structures are located at this level, such as: (a) junction of larynx and trachea, (b) junction of pharynx and oesophagus, and (c) anterior tubercle of transverse process of C6 vertebra (carotid tubercle) against which common carotid artery can be compressed.
9. **First tracheal ring** : It can be felt by gentle pressure just above the isthmus of the thyroid gland.
10. **Isthmus of the thyroid gland** : It lies in front of the 2nd, 3rd, and 4th tracheal rings.
11. **Inferior thyroid veins** : After emerging from isthmus, they run downwards to lie in front of the 5th, 6th, and 7th tracheal rings.

12. **Thyroidea ima artery** : When present, it ascends in front of trachea to the isthmus of the thyroid; it usually arises from the brachiocephalic artery.
13. **Jugular venous arch** : This transverse venous arch, connects the two anterior jugular veins just above the suprasternal notch.
14. **Suprasternal notch** : It can be felt between the anterior ends of the clavicle. It lies opposite the lower border of the body of T2 vertebra. Occasionally, left brachiocephalic vein and brachiocephalic artery may lie in front of trachea in the suprasternal notch.

**FIG. 6.2** ■ Structures in the anterior midline of the neck.

## CLINICAL CORRELATION

- **Most common anterior midline swellings of the neck:** these are: (a) enlarged submental lymph nodes, (b) thyroglossal cyst, and (c) goitre.
- **Tracheostomy:** it is most commonly done in the retrothyroid region after cutting the isthmus of thyroid gland (for details, see [Chapter 11](#) ,

page 162).

- **Cut throat wounds:** these are most commonly observed just above or below the hyoid bone. The main vessels of the neck, namely common carotid, internal and external carotid arteries, and internal jugular vein, usually escape the injury because they are automatically pushed backwards to the deeper plane, when neck is inadvertently extended by the culprit, before being cut.

## **Anterior triangle of the neck AN 32.1**

The anterior triangle of the neck is a large triangular space on each side of the neck, in front of sternocleidomastoid with its apex directed downwards and base directed upwards ([Fig. 6.3](#) ).

**FIG. 6.3 ■** Boundaries and subdivisions of the right anterior triangle of neck. The subdivisions are labelled in *bold colour* .

### **Boundaries (Fig. 6.3 )**

*Anterior:* Anterior median line of the neck.

*Posterior:* Anterior border of the sternocleidomastoid muscle.

*Base:* Lower border of the body of mandible and a line extending from the angle of mandible to the mastoid process.

*Apex:* Suprasternal notch at the meeting point between anterior border of sternocleidomastoid and anterior median line.

*Roof:* Investing layer of deep cervical fascia.

The superficial fascia over the fascial roof contains platysma in the upper and anterior parts. The cervical branch of facial nerve and ascending and descending branches of transverse cervical cutaneous nerve traverse the plane between the platysma and the fascial roof of the triangle.

### **Subdivisions AN 32.1**

For convenience of description, the anterior triangle has been subdivided, by the digastric muscle and superior belly of omohyoid muscle, into the following three and half triangles ([Fig. 6.3](#)):

1. ***Submental triangle (half only)***
2. ***Digastric (submandibular) triangle***
3. ***Carotid triangle***
4. ***Muscular triangle .***

The **suprahyoid area** includes submental and digastric triangles. While **infrahyoid area** includes right and left muscular triangles.

Before studying subdivisions of anterior triangle, it is appropriate for students to know the attachments of digastric and omohyoid muscles, which are used for its subdivision.

### **Digastric muscle ([Fig. 6.5 A](#))**

It has two bellies: posterior and anterior. The large posterior belly arises from the digastric notch on the medial surface of the base of the mastoid process, and runs downwards and forwards, towards the hyoid bone.

The narrow anterior belly arises from digastric fossa on the base of the mandible near symphysis menti and runs downwards and backwards, towards the hyoid bone. Above the hyoid bone, the two bellies are connected by an intermediate tendon, which is anchored to the hyoid bone by a fascial sling of investing layer of deep cervical fascia.

### **Omohyoid muscle ([Fig. 6.9](#)) AN 29.4**

It consists of superior and inferior bellies joined at an angle by an intermediate tendon. The *inferior belly* arises from upper border of scapula, near the suprascapular notch, it then passes behind the sternocleidomastoid and ends in an intermediate tendon. The *superior belly* begins at the intermediate tendon and passes almost vertically upwards to be attached to the lower border of the hyoid bone. The *intermediate tendon* lies at the level of arch of cricoid cartilage and anchored to the clavicle by fascial sling derived from investing layer of deep cervical fascia.

### **Submental triangle (Fig. 6.4 ) AN 32.2**

It is actually a median triangle on the front of neck below the chin and above the hyoid bone. It thus occupies upper portions of both the anterior triangles.

**FIG. 6.4 ■** Boundaries and contents of the submental triangle.

### **Boundaries**

*On each side:* Anterior belly of digastric muscle

*Base:* Body of hyoid bone

*Apex:* Chin or symphysis menti.

### **Floor**

It is formed by two mylohyoid muscles meeting at the median fibrous raphe

extending from symphysis menti to the hyoid bone.

### Roof

Investing layer of deep cervical fascia.

### Contents

1. Submental lymph nodes (three or four in number). Efferents from these nodes pass to the submandibular lymph nodes.
2. Submental veins and commencement of anterior jugular veins.

### N.B.

The contents of the triangle actually lie in the superficial fascia over the roof of the submental triangle.

### CLINICAL CORRELATION

**Enlargement of submental lymph nodes:** Infections of floor of mouth, tip of tongue, and lower incisor teeth cause painful enlargement of submental lymph nodes because lymph from these structures is drained into these nodes.

### **Digastric (submandibular) triangle (Fig. 6.5 A and B) AN 32.2**

It is so named because it is located between the two bellies of the digastric muscle and below the base of the mandible.

**FIG. 6.5 ■** Digastric (submandibular) triangle: ( **A** ) boundaries and floor; ( **B** ) boundaries and contents.

## Boundaries

*Anteroinferiorly:* Anterior belly of digastric muscle.

*Posteriorly:* Posterior belly of digastric muscle, supplemented by stylohyoid muscle.

*Base:* It is formed by the base of the mandible and imaginary line joining the angle of the mandible to the mastoid process.

*Apex:* It is formed by the intermediate tendon of the digastric muscle, being bound down to hyoid bone by a fascial sling derived from investing layer of deep cervical fascia.

## Floor

It is formed by mylohyoid (anteriorly), hyoglossus, and small part of the middle constrictor (posteriorly).

## Roof

It is formed by investing layer of deep cervical fascia, which splits to enclose the submandibular salivary gland. In the superficial fascia over the roof lies platysma, cervical branch of facial nerve and ascending branch of transverse cervical nerve.

## Contents

The digastric triangle is subdivided into anterior and posterior parts.

### ***Contents in the anterior part of the triangle:***

- Large superficial part submandibular salivary gland
- Submandibular lymph nodes
- Hypoglossal nerve
- Facial vein (lies superficial to the gland)
- Facial artery (lies deep to the gland)
- Submental artery
- Mylohyoid nerve and vessels.

### ***Contents in the posterior part of the triangle:***

- Lower part of parotid gland
- External carotid artery
- Carotid sheath and its contents
- Structures passing between the external and internal carotid

arteries (for details, refer to page 235).

Most of these structures are discussed in detail in the submandibular region ([Chapter 9](#)).

### CLINICAL CORRELATION

**Submandibular triangle is the common site of swellings** because of: (a) *involvement of submandibular lymph nodes* as they drain lymph from widespread areas such as anterior two-third of tongue (except tip), floor of mouth, frontal, ethmoidal, and maxillary air sinuses and (b) *enlargement of the submandibular gland*. The efferents from submandibular lymph nodes mostly pass to jugulo-omohyoid and partially to jugulodigastric nodes situated along the internal jugular vein.

### **Carotid triangle (Fig. 6.6 ) AN 32.2**

It is so called because it contains all the three carotid arteries, namely common carotid, internal carotid, and external carotid.

**FIG. 6.6 ■** Carotid triangle: ( **A** ) boundaries and floor; ( **B** ) boundaries and contents.

It is the site for carotid embolism and carotid body tumour.

## **Boundaries**

*Anterosuperiorly:* Posterior belly of digastric supplemented by stylohyoid

*Anteroinferiorly:* Superior belly of omohyoid

*Posteriorly:* Anterior border of sternocleidomastoid.

## **Roof**

It is formed by investing layer of deep cervical fascia. The superficial fascia over the roof contains platysma, cervical branch of facial nerve and transverse cervical nerve (a cutaneous branch of the cervical plexus).

## **Floor**

It is formed by the following four muscles:

1. Thyrohyoid
2. Hyoglossus
3. Middle constrictor
4. Inferior constrictor.

## **Contents**

1. Carotid arteries
  - (a) Common carotid artery
  - (b) Internal carotid artery
  - (c) External carotid artery and its first five branches
2. Carotid sinus and carotid body
3. Internal jugular vein
4. Last three cranial nerves:
  - (a) Vagus nerve
  - (b) Spinal accessory nerve
  - (c) Hypoglossal nerve
5. Carotid sheath
6. Ansa cervicalis
7. Cervical part of the sympathetic chain
8. Deep cervical lymph nodes.

## N.B.

The major contents of carotid triangle are common carotid artery, internal carotid artery, external carotid artery, internal jugular vein, and last three cranial nerves, all overlapped by sternocleidomastoid.

The carotid triangle provides good view of all its contents only if sternocleidomastoid is retracted slightly backwards.

## Relevant features of the contents of the carotid triangle

### Common carotid artery

It ascends from just behind the inferior angle of the carotid triangle in the carotid sheath under cover of anterior border of sternocleidomastoid and in front of lower four cervical transverse processes and at the level of the upper border of the thyroid cartilage divides into external and internal carotid arteries. The common carotid artery gives no other branches in the neck (for details, see [Chapter 16](#) , page 231).

### Internal carotid artery

It runs straight upwards as the continuation of the common carotid artery.

## N.B.

The common carotid artery and its continuation, the internal carotid artery can be represented in living body by a straight line from sternoclavicular joint to the retromandibular fossa.

## CLINICAL CORRELATION

- **Compression of common carotid artery:** The common carotid artery can be compressed against the prominent anterior tubercle of transverse process of the 6th cervical vertebra called *carotid tubercle* (*Chassaignac's tubercle* ) by pressing medially and posteriorly with the thumb. The carotid tubercle of the 6th cervical vertebra is approximately 4 cm above the sternoclavicular joint.
- **Carotid pulse (neck pulse):** It can be felt by palpating, either common carotid artery by putting index and middle fingers, posterolateral to the larynx at the upper border of thyroid cartilage; or external carotid artery by putting index and middle fingers posterolateral to the upper part of larynx midway between superior border of thyroid cartilage and greater

cornu of hyoid bone. *The carotid pulse is one of the strongest pulses in the body and routinely checked during cardiopulmonary resuscitation (CPR)* . Clinically, the absence of carotid pulse suggests **cardiac arrest**.

## External carotid artery

It ascends anteromedial to the internal carotid artery and gives the following five branches in the triangle:

1. Ascending pharyngeal artery (first branch)
  2. Superior thyroid artery
  3. Lingual artery
  4. Facial artery
  5. Occipital artery.
- **Ascending pharyngeal artery:** It is a slender artery that arises from the medial aspect of external carotid artery near its lower end. It ascends in the deeper plane on the side of the pharynx (for details, see [Chapter 16](#) page 233).
  - **Superior thyroid artery:** It arises from the front and descends downwards and forwards to pass deep to the infrahyoid muscles to reach the upper part of the thyroid gland (for details, see [Chapter 16](#) , page 231).
  - **Lingual artery:** It arises from the front aspect of external carotid artery, opposite the tip of greater cornu of hyoid bone. It then runs upwards and forwards forming a characteristic loop over the greater cornu of the hyoid and disappear deep to the hyoglossus muscle. Before disappearing, it gives rise to suprahyoid artery, which runs superficial to hyoglossus above the hyoid (for details, see page 232).

## N.B.

The loop of lingual artery above the greater cornu of hyoid bone permits free movements of hyoid bone without damaging the artery.

- **Facial artery:** It arises from the front aspect of external carotid artery just above the lingual artery and runs upwards on the superior constrictor deep to digastric and stylohyoid muscles (for details, see page 232).
- **Occipital artery:** It arises from the posterior aspect of external carotid artery at the lower border of posterior belly of digastric muscle and runs backwards superficial to internal carotid artery, internal

jugular vein, and last three cranial nerves along the lower border of posterior belly of digastric (for details, see [Chapter 9](#) , page 119).

### Hypoglossal nerve

It descends between the internal jugular vein and internal carotid artery. Then just above the level of greater cornu of hyoid bone, it hooks around the origin of the occipital artery, runs forwards, crossing in front of internal carotid artery, external carotid artery and loop of lingual artery to run on the hyoglossus muscle above the hyoid bone.

As it crosses the internal carotid artery, it gives off the superior root of ansa cervicalis (also called *descendens hypoglossi* ), which descends on the anterior wall of the internal and common carotid arteries and becomes embedded in the anterior wall of the carotid sheath.

### Deep cervical lymph nodes

They lie on and along the internal jugular vein (for details, see page 242).

### Internal jugular vein

It is partly hidden by the posterior edge of the sternocleidomastoid. It descends posterolateral to common and internal carotid arteries and receives the following three veins in the region of carotid triangle:

1. Lingual vein
  2. Common facial vein
  3. Superior thyroid vein.
- The **lingual vein** lies just below and parallel to the hypoglossal nerve, crosses external and internal carotid arteries to join the internal jugular vein.
  - The **common facial vein**, after crossing the digastric triangle, crosses the upper part of carotid triangle to drain into the internal jugular vein.
  - The **superior thyroid vein** crosses the lower part of the triangle to end into the internal jugular vein.

### Vagus nerve

It descends vertically downwards, first between the internal carotid artery and internal jugular vein and then between common carotid artery and internal jugular vein. It gives the following two branches in the carotid triangle:

1. **Pharyngeal branch:** It runs inferomedially between external and internal carotid arteries to join the pharyngeal plexus on the middle constrictor of the pharynx.
2. **Superior laryngeal nerve:** It runs on a deep plane, deep to both internal and external carotid arteries, where it divides into internal and external laryngeal nerves. The internal laryngeal nerve (sensory) passes forwards to disappear deep to thyrohyoid muscle; there it pierces the thyrohyoid membrane to supply the laryngeal mucosa.

The external laryngeal nerve (motor) descends to supply the inferior constrictor and cricothyroid muscles after passing deep to the superior belly of the omohyoid.

### Accessory nerve

It runs downwards and backwards across the upper part of the triangle, superficial to the internal jugular vein to enter the sternocleidomastoid muscle, which it supplies.

### Carotid sheath

It is a fascial sheath, which encloses internal jugular vein, and internal and common carotid arteries. The vagus nerve lies in between the vein and the artery on a deeper plane (for details, refer to [Chapter 4](#)). The ansa cervicalis is embedded in its anterior wall, whereas the cervical sympathetic chain lies just deep to its posterior wall on the prevertebral fascia.

### Carotid sinus

It is a fusiform dilatation at the terminal end of common carotid artery or at the beginning of internal carotid artery. It has rich innervation from glossopharyngeal, vagus, and sympathetic nerves. The carotid sinus acts as a baroreceptor (pressure receptor) and regulates the blood pressure in the cerebral arteries.

### Carotid body

It is a small oval structure situated behind the bifurcation of the common carotid artery. It is reddish-brown and receives rich nerve supply from glossopharyngeal, vagus, and sympathetic nerves. It acts as a chemoreceptor and responds to the changes in the oxygen and carbon dioxide content of the blood. The excess of  $\text{PCO}_2$  (hypercapnoea) and reduced  $\text{PO}_2$  tension in blood

(hypoxia) stimulate it, to cause increased in blood pressure, heart rate and respiratory rate.

Thus carotid body regulates cardiovascular and respiratory function.

## **CLINICAL CORRELATION**

**Carotid sinus syndrome:** In an individual with *carotid sinus hypersensitivity*, pressure on carotid sinuses can cause enough slowing of heart rate, fall in blood pressure and cerebral ischaemia that will lead to fainting (syncope). Individuals with hypersensitive carotid sinuses may often have sudden attacks of syncope on rotation of head especially when wearing a shirt with tight collar or a tie with tight knot, condition called **carotid sinus syndrome**. Symptoms can be relieved by periarterial neurectomy.

- **Carotid body tumours:** They are painless, slow growing tumours. They may attain large size and infiltrate nearby nerves and vessels to cause death.

## **Ansa cervicalis (Figs 6.7 and 6.8 )**

The ansa cervicalis (ansa hypoglossi) is a U-shaped nerve loop present in the region of the carotid triangle embedded in the anterior wall of the carotid sheath. It is derived from ventral rami of C1, C2, and C3 spinal nerves. It supplies all the infrahyoid muscles except thyrohyoid, which is supplied by nerve to thyrohyoid (C1) from hypoglossal nerve.

**FIG. 6.7 ■** Formation and distribution of the ansa cervicalis.

**FIG. 6.8 ■** Location and relations of the ansa cervicalis.

## Roots

Ansa cervicalis has the following two roots:

1. **Superior root (descendens hypoglossi)** is formed by the descending branch of the hypoglossal nerve carrying C1 spinal nerve fibres. It descends downwards over internal and common carotid

arteries.

2. **Inferior root (descendens cervicalis)** is derived from C2 and C3 spinal nerves. As this root descends, it first winds round the internal jugular vein and then continues anteroinferiorly to join the superior root in front of the common carotid artery at the level of cricoid cartilage.

## Distribution

1. Superior root gives branch to superior belly of omohyoid.
2. Dependent loop gives branches to sternohyoid, sternothyroid, and inferior belly of the omohyoid.

## Functional significance

It innervates infrahyoid muscles which are important in maintaining phonation and deglutition.

## CLINICAL CORRELATION

- Part of it is used as a nerve graft to join the cut ends of recurrent laryngeal nerve. The left recurrent laryngeal nerve is commonly cut during thyroidectomy.
- Being located deep in the carotid triangle of neck, it is commonly injured in surgical procedures of neck such as radical dissection of neck.

## Muscular triangle (Figs 6.1 and 6.3 ) AN 32.2

### Boundaries

*Anterior:* Anterior median line of the neck, extending from hyoid bone to the suprasternal notch

*Anterosuperior:* Superior belly of the omohyoid

*Posteroinferior:* Anterior border of sternocleidomastoid.

### Floor

It is formed by sternothyroid, sternohyoid, and thyrohyoid muscles.

### Roof

It is formed by investing layer of deep cervical fascia. The superficial fascia

over the roof contains anterior jugular vein and associated lymph nodes.

## Contents

Infrahyoid muscles, namely sternothyroid, sternohyoid, and thyrohyoid.

The important deeper structures in the region of muscular triangle are thyroid gland, trachea, and oesophagus. They are studied separately.

Therefore the knowledge of this triangle is important in *thyroidectomy* and *tracheostomy*.

The infrahyoid area contains strap (ribbon-like) muscles of the neck. Underneath these muscles lie all important structures. From superficial to deep, these are as follows:

1. Thyroid and parathyroid glands
2. Larynx and trachea
3. Hypopharynx (laryngopharynx) and oesophagus.

## Infrahyoid muscles of the neck (strap muscles of the neck)

The infrahyoid muscles are ribbon-like and comprise the following four paired muscles ([Fig. 6.9](#)):

1. Sternothyroid
2. Sternohyoid
3. Thyrohyoid
4. Omohyoid.

**FIG. 6.9 ■** Origin and insertion of the infrahyoid muscles.

### **N.B.**

Developmentally, the infrahyoid muscles are the derivatives of the longitudinal muscle sheet that extends vertically from the symphysis menti to pubic symphysis. This sheet ultimately divides into different segments; some of them disappear altogether. The remaining segments are represented by:

- (a) Geniohyoid, above the hyoid
- (b) Infrahyoid muscles, between the hyoid and sternum
- (c) Sternalis (occasional) in front of sternum
- (d) Rectus abdominis and pyramidalis (occasional) in the anterior abdominal wall

The attachment of inferior belly of omohyoid to scapula is secondary to its migration from its initial attachment to medial end of the clavicle.

The **infrahyoid muscles** are arranged into two layers with two muscles in each layer, namely

- 1. Superficial layer
  - (a) Sternohyoid
  - (b) Omohyoid
- 2. Deep layer
  - (a) Sternothyroid
  - (b) Thyrohyoid.

### **Nerve supply**

All are supplied by ventral rami of C1, C2, and C3 spinal nerves.

The sternohyoid, omohyoid, and thyrohyoid are supplied by ansa cervicalis

and its superior root. The thyrohyoid is innervated directly by a branch from the hypoglossal nerve carrying fibres of ventral ramus of C1. The origin, insertion, and actions of individual muscles are presented in [Table 6.1](#).

 **TABLE 6.1**

### Origin, insertion, and actions of infrahyoid muscles AN 29.4

Muscle	Origin	Insertion	Actions
<b><i>Sternohyoid</i></b> (thin narrow strap muscle)	Posterior surface of manubrium and adjoining part of clavicle, and posterior sternoclavicular ligament	Medial part of the lower border of the hyoid bone	Depresses hyoid bone following its elevation during swallowing
<b><i>Sternothyroid</i></b> (shorter and wider than sternohyoid)	Posterior surface of the manubrium and adjoining part of the first costal cartilage	Oblique line on the lamina of thyroid cartilage	Depresses the larynx following its elevation during phonation and terminal phase of swallowing
<b><i>Thyrohyoid</i></b> (it is an upward extension of the sternothyroid being broken by the oblique line on the thyroid lamina)	Oblique line on the lamina of thyroid cartilage	Lower border of the greater cornu and adjoining part of the body of the hyoid bone	<ul style="list-style-type: none"> <li>• Depresses the hyoid bone during swallowing</li> <li>• Elevates the larynx when hyoid bone is</li> </ul>

			fixed by suprahyoid muscles
<b><i>Omothyoid</i></b> (consists of inferior and superior bellies united by an intermediate tendon)	<ul style="list-style-type: none"> <li>• <b><i>Inferior belly</i></b> from upper border of scapula near the suprascapular notch and occasionally from superior transverse scapular ligament</li> <li>• <b><i>Superior belly</i></b> proceeds upwards from the intermediate tendon almost vertically upwards near the lateral border of sternohyoid</li> </ul>	Lower border of the body of the hyoid bone lateral to the sternohyoid; the intermediate tendon is bound to the clavicle by a fascial pulley derived from investing layer of deep cervical fascia	Depresses the hyoid bone following its elevation during swallowing

### N. B.

All the infrahyoid muscles depress the hyoid bone following its elevation during swallowing.

The thyrohyoid also elevates the larynx when the hyoid is fixed by the suprahyoid muscles.

### Golden Facts to Remember

• <b>Most important pressoreceptor in the body</b>	Carotid sinus

• <b>Most important landmark in the neck</b>	Cricoid cartilage
• <b>Commonest site of tracheostomy</b>	Retrothyroid (i.e., behind the isthmus of thyroid gland)
• <b>Carotid tubercle (Chassaignac's tubercle)</b>	Prominent anterior tubercle of the transverse process of 6th cervical vertebra
• <b>Carotid pulse/neck pulse</b>	Strongest arterial pulse felt posterolateral to larynx at the upper border of thyroid cartilage
• <b>All the strap muscles of the neck are supplied by the branches of ansa cervicalis</b>	Thyrohyoid muscle, which is supplied by a branch of hypoglossal nerve carrying C1 fibres
• <b>Arteriosclerosis of common carotid and/or internal carotid artery can cause</b>	Cerebrovascular ischaemia (cerebral stroke)
• <b>Function of carotid body</b>	Modulation of cardiovascular and respiratory functions
• <b>Potato tumour</b>	Tumour arising from carotid body (also called <i>carotid body tumour</i> )

## CLINICAL CASE STUDY

### Case I

A 35-year-old man complained to his physician that he is a victim of sudden attacks of syncope (fainting) from sudden rotation of his head, especially when wearing a tight collar or tie. He was told by the physician that he was suffering from a disease called **carotid sinus syndrome** and a surgical procedure may be needed to relieve his symptoms.

### Questions

1. What is carotid sinus?
2. What are the functions of carotid sinus?
3. Mention the nerve supply of the carotid sinus.
4. Mention the surgical procedure performed to relieve the symptoms.

### Answers

1. It is a fusiform dilatation in the terminal part of common carotid artery and the commencement of internal carotid artery.
2. It is the main pressoreceptor of the body and regulates the blood pressure in the cerebral arteries.
3. (a) Carotid sinus branch of glossopharyngeal nerve and (b) twigs from vagus and cervical sympathetic chain.
4. Periarterial neurectomy.

## **Case II**

A 75-year-old man visited his physician and complained that he is having a small painless swelling below his chin and his tip of tongue is ulcerated. On examination, the physician found that the swelling was single and located in the submental triangle. It was hard, mobile, and not attached to the skin.

## **Questions**

1. What are the boundaries of the submental triangle?
2. Give the number of lymph nodes located in this triangle.
3. Name the structures drained by submental lymph nodes.
4. Name the veins which commence in the submental triangle.

## **Answers**

1. Refer to Submental Triangle on page 88.
2. Three or four.
3. Floor of mouth, incisor teeth, and tip of tongue.
4. Anterior jugular veins.

---

# Chapter 7: Back of the neck, suboccipital region, cervical spinal column and joints of neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the boundaries and contents of suboccipital triangle. **AN 42.2**
- Describe the position, direction of fibres, relations, nerve supply, and actions of semispinalis capitis and splenius capitis. **AN 42.3**
- Describe and demonstrate the movements and muscles producing them at atlanto-occipital and atlanto-axial joints. **AN 43.1**
- Write short notes on: (a) ligamentum nuchae, (b) atlanto-occipital joint, (c) atlanto-axial joint, and (d) dorsal ramus of C1.
- Give the anatomical basis of: (a) neck rigidity, (b) cisternal puncture, (c) hangman's fracture, and (d) cervical spondylosis.

## Back of the neck

The back of the neck is limited above by external occipital protuberance and superior nuchal lines, and below by spine of C7 vertebra and horizontal lines extending on either side from it to the acromial process of scapula.

The important structures on the back of the neck include ligamentum nuchae, extensor muscles of the neck, suboccipital triangle, and arterial anastomosis around the semispinalis capitis.

The structures encountered in the suboccipital region during surgical procedure/dissection are shown in [Figure 7.1](#).

**FIG. 7.1** ■ Dissection of suboccipital region showing superficial structures on the left side and deep structures on the right side.

## Surface landmarks

1. **External occipital protuberance** : It is a bony projection felt at the upper end of the **nuchal furrow** – a vertical groove in the midline on the back of the neck.
2. **Superior nuchal lines** : These are curved bony ridges passing laterally from external occipital protuberance. Their convexity faces upwards.
3. **Spine of 7th cervical vertebra** : It is knob-like bony projection felt at the lower end of the nuchal furrow. The spines of other cervical vertebrae are covered by *ligamentum nuchae*, and hence cannot be felt.
4. **Acromion process** : It is felt as a bony edge immediately above the bulge of the deltoid muscle.

## Soft tissues on the back of the neck

The soft tissues on the back of the neck are divided into four layers. From superficial to deep, these are as follows:

1. Skin (cutaneous innervation)
2. Superficial fascia
3. Deep fascia
4. Muscles.

### Skin

The skin on the back of the neck is supplied by the medial branches of the dorsal rami of C2, C3, and C4 spinal nerves. (The dorsal ramus of the C1 does not divide into medial and lateral branches and does not give a cutaneous branch.)

The cutaneous nerves derived from the medial branches of dorsal rami of C2, C3, and C4 are as follows ([Fig. 7.1](#)):

1. **Greater occipital nerve (C2)** : It pierces the deep fascia on the level with the superior nuchal line 2.5 cm lateral to the external occipital protuberance and supply the posterior part of the scalp as far as the vertex. It is the **thickest cutaneous nerve** in the body.
2. **Third occipital nerve (C3)** : It pierces the deep fascia medial to the greater occipital nerve, a little below the superior nuchal line. It is a small cutaneous nerve and supplies the skin of the nape of the neck up to the external occipital protuberance.
3. **Cutaneous branches of C4 and C5** : These branches pierce the deep fascia close to the midline in series with the 3rd occipital nerve. They supply the adjacent skin.

### Superficial fascia

The **superficial fascia** (subcutaneous tissue) of the back is thick and in spite of its fat content, it is very tough. It contains cutaneous nerves and vessels. The cutaneous nerves are greater occipital, third occipital, and cutaneous branch of C4 and C5 (described earlier).

The cutaneous vessels are **occipital artery** and minute twigs derived from second part of the vertebral artery. The occipital artery appears 2.5 cm from midline and accompanies the greater occipital nerve.

## Deep fascia

The deep fascia of the back is called **nuchal fascia** . It is attached in the median plane to the spines, supraspinous ligaments, and ligamentum nuchae. Extending laterally, it sheaths the muscles of the back.

### Ligamentum nuchae (Fig. 7.2 )

It is a triangular sheet of fibroelastic tissue that forms the median fibrous septum between the muscles of the two sides of the back of the neck.

**FIG. 7.2 ■** Ligamentum nuchae.

The ligamentum nuchae presents three borders:

1. **Superior border** attached to the external occipital crest.

2. **Anterior border** attached to the posterior tubercle of atlas and the spines of the cervical vertebrae (C2–C7).
3. **Free posterior border** , which extends from the external occipital protuberance to tip of the spine of the 7th cervical vertebra.

### N.B.

In quadrupeds, the ligamentum nuchae is a well-developed powerful elastic structure, which supports the heavy head against the gravity. In human beings, it is not that powerful and contains little elastic tissue.

## Muscles

The muscles of the back of the neck on either side of midline are arranged into **superficial and deep groups**:

1. **Superficial group** : The muscles of this group are arranged into two layers:
  - (a) *First (or superficial) layer* consisting of trapezius muscle.
  - (b) *Second (or deep) layer* consisting of levator scapulae, rhomboideus minor, and rhomboideus major.
2. **Deep group** : The muscles of this group form the *intrinsic musculature* . The intrinsic muscles are arranged in four layers; from superficial to deep, these are as follows:
  - (a) *External layer* consisting of splenius capitis and splenius cervicis muscles
  - (b) *Intermediate layer* consisting of longissimus capitis and longissimus cervicis muscles
  - (c) *Deep layer* consisting of semispinalis capitis and semispinalis cervicis muscles
  - (d) *Deepest layer* consisting of suboccipital muscles.

### Trapezius (Fig. 7.3 )

The trapezius is a large, flat, triangular muscle, which is placed superficially on the back of the neck and thorax. It forms the sloping ridge of the neck. The trapezius muscles of two sides together form the **trapezium** (Greek word meaning irregular four-sided figure), hence the name trapezius.

**FIG. 7.3 ■** Origin and insertion of the trapezius. The latissimus dorsi is also shown.

## Origin

It arises from the medial third of the superior nuchal line, external occipital protuberance, ligamentum nuchae, spine of C7, and spines of all the thoracic vertebrae.

## Insertion

1. *Upper fibres* sweep downwards to be inserted into the posterior border and upper surface of the lateral third of the clavicle.
2. *Middle fibres* run horizontally to be inserted into the medial border of the acromion and the upper lip of the spine of the scapula.
3. *Lower fibres* ascend to be inserted into the tubercle of the spine of the scapula near its root.

## Nerve supply

It is supplied by:

1. Spinal accessory nerve (motor)
2. Ventral rami of C3 and C4 (sensory).

## Actions

1. The uppermost fibres together with the levator scapulae elevate the shoulder and are thus responsible for shrugging the shoulder.
2. The middle and lower parts of the muscles act with the rhomboids in retracting and steadying the scapula.

The muscles of second layer of superficial group are described in detail in *Textbook of Anatomy: Upper Limb and Thorax*, Vol. I, 4ed., by Vishram Singh.

## **Splenius capitis muscle (Fig. 7.4 ) AN 42.3**

### Origin

It arises from spines of 7th cervical and upper four thoracic vertebrae and lower portion of the ligamentum nuchae.

**FIG. 7.4 ■** Origin and insertion of the splenius capitis.  
The part of splenius cervicis is also seen.

### Insertion

It runs upwards and laterally, and emerges from beneath the trapezius in the posterior triangle and inserts into the mastoid process and lateral third of the superior nuchal line.

### Nerve supply

It is supplied by posterior rami of middle cervical nerves.

### Actions

It rotates the head and face to the same side. Acting bilaterally, they draw head backwards and extend the neck.

### Splenius cervicis muscle

#### Origin

It arises from spines of T3–T6 thoracic vertebrae.

#### Insertion

It passes deep to splenius capitis, to be inserted into the transverse process of the upper four cervical vertebrae.

### Nerve supply

It is supplied by posterior rami of lower cervical nerves.

### Actions

It turns the head and face towards the same side. Acting bilaterally, they extend the head and neck.

### N.B.

The splenius (splenius capitis and splenius cervicis together) lies deep to trapezius and sternocleidomastoid and superficial to semispinalis capitis and levator scapulae. It binds the deep extensors of the back of the neck like a bandage, hence the name splenius (L. *splenius* = bandage).

### Longissimus capitis muscle (Fig. 7.5 )

#### Origin

It arises from transverse processes of the lower four cervical vertebrae.

**FIG. 7.5** ■ Origin and insertion of the longissimus capitis.

## Insertion

It inserts into the mastoid process, deep to the splenius capitis.

## Nerve supply

It is supplied by posterior rami of lower cervical nerves.

## Actions

It extends the head and turns the face to the same side.

## Semispinalis capitis muscle (Fig. 7.6 ) AN 42.3

It is long, thick powerful muscle and produces longitudinal bulging of the neck on each side of the median furrow. Its medial border is free and is in contact with the ligamentum nuchae (Fig. 7.6 ).

**FIG. 7.6 ■** Origin and insertion of the semispinalis

capitis.

### Origin

It arises from transverse processes of lower four cervical and upper six thoracic vertebrae (C4–T6).

### Insertion

It runs vertically upwards and inserted into the medial part of the area between the superior and inferior nuchal lines of the occipital bones.

### Nerve supply

It is supplied by posterior rami of spinal nerves, usually by medial branches.

### Actions

It extends the head.

### **Semispinalis cervicis muscle (Fig. 7.6 )**

It lies deep to the lower fibres semispinalis capitis.

### Origin

It arises from transverse processes of lower cervical and upper thoracic vertebrae (C5–T4).

### Insertion

Spines of cervical vertebrae (C2–C4).

### Nerve supply

It is supplied by posterior rami of spinal nerves, usually by medial branches.

### Action

It extends the neck.

### CLINICAL CORRELATION

**Neck rigidity:** The *neck rigidity* occurs in meningitis because of spasm of extensor muscles on the back of the neck. This is caused by *irritation of nerve roots of cervical spinal nerves* during their passage through the subarachnoid space, which is infected in this disease. The basic flexion of

neck causes pain as the nerves are stretched.

## Suboccipital region

The suboccipital region is limited *above* by inferior nuchal line of occipital bone; *below* by massive spine and laminae of the axis vertebra; and *laterally* by the mastoid process and the transverse processes of atlas and axis vertebrae (Fig. 7.7).

**FIG. 7.7 ■** Schematic posterior view of the skull, showing bony boundaries of suboccipital region and sites of the muscular attachments.

This region is clinically important because the neurosurgeons approach the posterior cranial fossa through this region.

### N.B.

This region lies beneath the semispinalis capitis, that is, underneath the apex of the posterior triangle on the side of the neck. It is important to remember that posterior triangle spirals from front to back, as a result its apex lies on the back of the neck.

## Suboccipital muscles

The suboccipital muscles (Fig. 7.8) are the short postural muscles that lie

deep in the suboccipital region. They connect the 1st cervical vertebra (atlas) to the 2nd cervical vertebra (axis), and connect both these vertebrae to the base of the skull. The suboccipital muscles cause extension of the head at the atlanto-occipital joints and rotation of head and atlas on the axis. They can act as extensors and rotators of the head but they function chiefly as postural muscles.

**FIG. 7.8 ■** Suboccipital muscles. Boundaries and floor of the suboccipital triangle are also seen.

On each side, following four muscles comprise the suboccipital group of muscles:

1. Rectus capitis posterior major
2. Rectus capitis posterior minor
3. Obliquus capitis inferior
4. Obliquus capitis superior.

All these muscles are supplied by the dorsal ramus of C1 spinal nerve (*suboccipital nerve* ). The origin, insertion, nerve supply, and actions of these muscles are enumerated in [Table 7.1](#) .

 **TABLE 7.1**

**Origin, insertion, and actions of suboccipital muscles \***

Muscles	Origin	Insertion	Actions
---------	--------	-----------	---------

<b><i>Rectus capitis posterior major</i></b>	From spine of axis by a pointed tendon	Passes upwards and laterally, and inserted by a broad base to the lateral part of the inferior nuchal line and area of bone below it	Extends the head at atlanto-occipital joint
<b><i>Rectus capitis posterior minor</i></b> (two minor muscles, one on each side, fills the triangular gap between diverging major muscles)	From posterior tubercle of the atlas	Passes upwards to be inserted into the medial part of the inferior nuchal line and area of bone below it	Extends the head at the atlanto-occipital joint
<b><i>Obliquus capitis inferior</i></b>	From spine of the axis	Passes laterally and slightly upwards to be inserted into the transverse process of the atlas	Rotates the head to the same side at the atlanto-axial joint
<b><i>Obliquus capitis superior</i></b>	From transverse process of the atlas	Passes upwards and backwards to be inserted into area between superior and inferior nuchal lines of the occipital bone, lateral to the semispinalis capitis; here it overlies the insertion of rectus capitis posterior major	Rotates the head to the same side (lateral flexion) at atlanto-axial joint; acting along with its counterpart of the opposite side, they extend the head at the atlanto-occipital joint

\* All suboccipital muscles are supplied by suboccipital nerve (dorsal ramus of C1)

### **CLINICAL CORRELATION**

The posterior cranial fossa is approached by neurosurgeons to remove the

brain tumour by clearing the suboccipital muscles and removing the exposed occipital bone.

### **Suboccipital triangle (Fig. 7.9 ) AN 42.2**

This is a triangular muscular space situated deep in the suboccipital region of the neck, one on each side of the midline and bounded by four suboccipital muscles.

**FIG. 7.9 ■** Boundaries and contents of the suboccipital triangle.

### **Boundaries (Fig. 7.8 )**

*Superomedial:* Rectus capitis posterior major, supplemented by rectus capitis posterior minor.

*Superolateral:* Obliquus capitis superior.

*Inferior:* Obliquus capitis inferior.

*Roof:* This is formed by dense fibrous tissue, and covered by semispinalis capitis medially and longissimus capitis and splenius capitis (occasionally) laterally.

*Floor:* The floor is formed by: (1) posterior arch of atlas and (2) posterior atlanto-occipital membrane.

### **Contents**

The contents of suboccipital triangle are as follows:

1. Suboccipital plexus of veins
2. Suboccipital nerve (dorsal ramus of 1st cervical nerve)
3. Third part of vertebral artery.

### N.B.

The vertebral artery and the dorsal ramus of the 1st cervical nerve lie in a groove on the upper surface of the posterior arch of the atlas. Here, artery is separated from arch by the nerve ([Fig 7.10](#) ).

### CLINICAL CORRELATION

**Cisternal puncture** is done when lumbar puncture fails to take out CSF sample for therapeutic and diagnostic purposes. Needle is introduced in the midline just above the spine of the axis vertebra. It pierces the posterior atlanto-occipital membrane at a depth of approximately 2 inches/5 cm in adults. Utmost care should be taken while introducing the needle because medulla lies only 1 inch anterior to the posterior atlanto-occipital membrane which, if damaged, may be fatal.

### 1. Suboccipital plexus of the veins

It lies in and around the suboccipital triangle. It connects the following veins:

- a. Muscular veins from neighbouring six muscles
- b. Occipital veins
- c. Internal vertebral venous plexus
- d. Condylar emissary vein from sigmoid sinus
- e. Deep cervical vein
- f. Plexus of the veins around vertebral artery.

Thus, it provides a number of alternative routes for venous drainage.

### CLINICAL CORRELATION

The connection between suboccipital venous plexus and internal vertebral venous plexus serves as a path of intracranial infection in *carbuncles of the neck*.

The *carbuncle* is an infective gangrene of subcutaneous tissue following infection of hair follicles.

### 2. Dorsal ramus of first cervical nerve (also called *suboccipital*

## nerve )

It emerges backwards between the vertebral artery and the posterior arch of the atlas and soon breaks up into five muscular branches to supply four suboccipital muscles (rectus capitis posterior major, rectus capitis posterior minor, obliquus capitis superior, and obliquus capitis inferior) and semispinalis capitis. The branch to inferior oblique joins the *greater occipital nerve*. It usually does not give any cutaneous branch (cf. unlike other spinal nerves, the 1st cervical spinal nerve has no sensory root).

### 3. Third part of the vertebral artery

The third part of the vertebral artery appears in the suboccipital triangle through foramen transversarium of the atlas vertebra. After emerging from the foramen, the artery winds backwards and medially behind the lateral mass of the atlas; lodges in a groove on the upper surface of its posterior arch, and finally leaves the triangle by passing deep to the thick lateral edge of the posterior atlanto-occipital membrane (oblique ligament of atlas) to enter the vertebral canal where it continues as the fourth part of the vertebral artery.

The vertebral artery is separated from the posterior arch of the atlas by the 1st cervical nerve and its dorsal and ventral rami.

### CLINICAL CORRELATION

The tortuous course of the third part of the vertebral artery in this region may serve to damp down the arterial pulsations within the cranial cavity.

But if it is affected by atheroma, movements of the head and neck may affect the flow of blood through it and cause temporary fainting or unconsciousness.

### Other Structures in Suboccipital Region

#### a. *First cervical nerve*

- The 1st cervical nerve while passing behind the lateral mass of atlas on its posterior arch. Here, it divides into dorsal and ventral rami (Fig. 7.10). Sometimes a small bony bridge is formed over dorsal ramus of C1 and vertebral artery, between lateral mass of atlas and the posterior arch. It is called *ponticulus ponticus*. Sometimes it may cause giddiness.
- The *dorsal ramus* of cervical nerve is already described.
- The **ventral ramus** winds forwards around the lateral mass and

lies medial or deep to the artery. It then descends in front of the root of the transverse process of the atlas between rectus capitis lateralis and rectus capitis anterior, which it supplies. Thereafter, it joins the ventral ramus of C2 to take part in the formation of cervical plexus.

**b. *Greater occipital nerve***

- It is the thickest cutaneous nerve of the head. It is medial branch of dorsal primary ramus of 2nd cervical spinal nerve. It arises from between 1st and 2nd cervical vertebrae. It winds around the middle of the lower border of the inferior oblique muscle, and runs upwards and medially. It crosses the suboccipital triangle and pierces the semispinalis capitis and trapezius muscles to supply the back of scalp up to the vertex.

**c. *Occipital artery in the suboccipital region***

- The occipital artery runs deep to the mastoid process and muscles attached to it, for example, sternocleidomastoid, splenius capitis, and longissimus capitis. The artery then crosses the rectus capitis lateralis, the superior oblique, and semispinalis capitis muscles at the apex of the posterior triangle. Finally, it pierces the trapezius 2.5 cm away from the midline and comes to lie along the greater occipital nerve. It presents a tortuous course in the superficial fascia of the scalp.
- Its branches in the region are: (1) mastoid, (2) meningeal, and (3) muscular.

**d. *Arterial anastomosis around semispinalis capitis muscle***

- One of the muscular branches is biggest – the **descending branch**, which divides into superficial and deep branches.
- The superficial branch anastomoses with the superficial branch of the transverse cervical artery superficial to the semispinalis capitis. The deep branch anastomoses with deep cervical artery, a branch of costocervical trunk deep to the semispinalis capitis.
- Thus, this *arterial anastomosis around the semispinalis capitis* is between external carotid artery (via occipital artery) and subclavian artery (via transverse cervical and costocervical trunk).

**FIG. 7.10** ■ Relationship of the third part of vertebral artery and 1st cervical nerve to the atlas vertebral as seen from the superior aspect.

## Cervical spinal column and joints of the neck

The cervical spinal column (Fig. 7.11) is generally referred to as **cervical spine** by the clinicians. It consists of seven cervical vertebrae and the intervening intervertebral discs. It is convex anteriorly. The cervical spine is a bony pillar of the neck, which supports the skull and transmits the weight. Within its cavity lies the spinal cord, roots of spinal nerves and covering meninges to which it provides protection. Because it is segmented, being made up of vertebrae and pads of fibrocartilage (intervertebral discs), it is a flexible structure and responsible for the mobility of the neck.

**FIG. 7.11 ■** Cervical vertebral column: (A) schematic diagram and (B) lateral radiograph. **AN 43.7**

Most of the problems on the back of the neck are due to involvement of cervical vertebrae and their joints. Therefore, it is very important for medical students to understand the anatomy of cervical spinal column in detail (also see [Chapter 8](#) , Vertebral Column in book *General Anatomy with Systemic Anatomy, Radiological Anatomy, Medical Genetics*, 4 ed. by Vishram Singh).

## Cervical vertebrae

Cervical vertebrae ([Fig. 7.11](#) ) are seven in number and numbered from above downwards. They are characterized by the presence of foramen in each of their transverse processes called **foramen transversarium** . It transmits vertebral artery ([Fig. 7.12](#) ), *except* for 7th cervical vertebra. First cervical vertebra is called **atlas** and the skull rests on it. It is named after mythological Greek Titan who was reputed to support the heavens on his shoulders. The 2nd cervical vertebra is called **axis** , because its odontoid process forms a pivot around which atlas rotates and carries the skull. The atlas and axis are specialized vertebrae. The *atlas has neither body nor spine* . It is ring-like and consists of two lateral masses, connected by a short anterior arch and long posterior arch ( [Fig. 2.33 A](#) ) . The axis possesses tooth-like odontoid process which projects upwards from the body. *The 3rd–6th cervical vertebrae are regarded as typical vertebrae* . The cervical vertebrae

are described in detail in [Chapter 2](#) , page 43.

**FIG. 7.12** ■ Typical cervical vertebra (superior aspect).

## Joints of the neck

The joints of the neck include intervertebral joints between the lower six cervical vertebrae and craniovertebral joints. The joints between the lower six cervical vertebrae are *typical cervical joints* . These are similar to those in the other parts of the vertebral column. They permit flexion, extension, and lateral bending but little rotation. The joints between 1st and 2nd cervical vertebrae and those between 1st cervical vertebrae and skull permit rotation and nodding of head, respectively. The joints of neck are clinically important because of high incidence of spondylosis, disc prolapse, and fracture dislocation in the cervical region.

### Typical cervical joints

These are the joints between lower six cervical vertebrae.

They include joints between the vertebral bodies and joints between vertebral arches.

### Joints between the vertebral bodies

They are of two types:

1. *Secondary cartilaginous joints (intervertebral disc)* between the

- bodies of adjacent vertebrae
2. *Synovial joints (joints of Luschka)* , between the lateral margins of the bodies of adjacent vertebrae.

### Secondary cartilaginous joints (**Fig. 7.13** )

These are articulations between two bodies of adjacent vertebrae from 2nd to 7th cervical vertebrae.

**FIG. 7.13** ■ Purely schematic diagram to show secondary cartilaginous joints (symphyses) between the vertebral bodies.

The adjacent articular surfaces are covered by the plates of hyaline cartilage and held together by an intervertebral disc.

The disc is fibrocartilaginous in nature. It consists of an outer part formed by a series of fibrocartilaginous laminae called **annulus fibrosus** and an inner part consisting of jelly-like material called **nucleus pulposus** . The most peripheral laminae of annulus fibrosus are formed of pure collagenous tissue, and on the front and on the back they blend with strong anterior and

weak posterior longitudinal ligaments. The discs are firmly bound to the edges of the hyaline cartilages and bodies of the vertebrae. The intervertebral discs are thick anteriorly in the cervical region contributing to the anterior convexity of the neck. No discs are found between the first two cervical vertebrae.

The intervertebral disc along with hyaline cartilage covering the upper and lower articular surfaces of the adjoining vertebral bodies form the **intervertebral symphysis** .

## Ligaments

### Anterior longitudinal ligament (Fig. 7.14 )

It extends anterior to the anterior arch of atlas and bodies of remaining cervical vertebrae. It is a strong ligament and consists of long and short fibres. The long fibres are superficial and bridge across several vertebrae whereas short fibres are deep and bridge across a single pair of vertebrae, and blend with the annulus fibrous of the intervertebral disc.

**FIG. 7.14** ■ Purely schematic diagram to show anterior longitudinal ligament.

### **Posterior longitudinal ligament (Fig. 7.15 )**

It runs longitudinally across the posterior surfaces of the cervical vertebrae and hence situated within the vertebral canal. Above, it is attached to the body of C2 (axis) vertebra and continues above as **membrana tectoria** . It is fairly wide where it is attached to the intervertebral discs but narrow over the bodies. It is loosely attached to the bodies to provide space for **basivertebral veins** and **paravertebral venous plexus** .

**FIG. 7.15** ■ Purely schematic diagram to show posterior longitudinal ligament.

It is weaker than anterior longitudinal ligament. Its superficial long fibres bridge across three or four vertebrae, whereas its short deep fibres extend between adjacent vertebrae as **perivertebral ligaments** and are attached to annulus fibrous of the disc.

### CLINICAL CORRELATION

**Prolapse of intervertebral disc in the cervical region:** It usually involves the disc between C5 and C6 or C6 and C7. The nucleus pulposus generally herniates in the posterolateral direction and compresses a nerve root. The herniated disc between C5 and C6 compresses C6 nerve root; hence, the patient feels pain in the thumb; whereas herniated disc between C6 and C7 compresses C7 nerve root and consequently there is pain, tingling, and numbness on the posterior aspect of arm, forearm, and middle and index fingers.

## Joints of Luschka (also called uncovertebral joints)

The lateral margins of vertebral bodies overlap the sides of intervertebral disc and directly articulate with each other to form small synovial joints of plane variety called **joints of Luschka**.

### CLINICAL CORRELATION

**Cervical spondylosis:** It is the most common clinical condition affecting the neck. Degenerative changes appear in the cervical spine, often during the third or fourth decade. The *disc space between 5th and 6th cervical vertebrae* is most frequently affected. The earliest changes are confined to the *intervertebral disc* but the *facet joints* and *uncovertebral joints (joints of Luschka)* get involved soon.

The joints of Luschka are the commonest sites of formation of *osteophytes* (seen as downward bony projections from the edges of vertebrae – *bony spurs*). Because cervical nerve roots lie posterolateral to these joints, they are often compressed by the osteophytes leading to pain along their distribution. The foramina transversaria containing vertebral artery lie lateral to these joints; hence, osteophytes can also cause distortion of vertebral artery leading to *vertebrobasilar insufficiency* which clinically presents as dizziness and allied symptoms following jerky neck movements.

## Joints between the vertebral arches

Joints between the vertebral arches include:

1. Joints between the articular processes of vertebrae (zygapophyseal joints).
2. Intervertebral syndesmoses between laminae, spines, and transverse processes.

## Zygapophyseal joints (also called facet joints)

These are joints between the superior and inferior articular processes of adjacent vertebrae ([Fig. 7.16](#)).

**FIG. 7.16 ■** Zygapophyseal joints between the superior and inferior articular processes of adjacent vertebrae.

## Type

These are synovial joints of plane variety. The articular surfaces are covered by hyaline cartilage.

The articular surfaces are inclined horizontally and slope inferiorly from anterior to posterior. This allows rotation of neck to look sideways and upwards.

## Ligaments

**Fibrous capsule :** It is thin and loose, and attached to the periphery of articular facets.

## Movements

It permits side-to-side rotation of the neck.

## CLINICAL CORRELATION

**Dislocation of vertebrae without fracture:** It occurs only in cervical region because of the inclination of the articular surfaces of articular processes. In thoracic and lumbar regions, dislocations are always associated with fracture of articular processes.

The dislocations mostly occur between 4th and 5th or between 5th and 6th

cervical vertebrae.

### Intervertebral syndesmoses

**Between the adjacent laminae ( Fig. 7.17 ) :** *Ligamenta flava* connect the laminae of adjacent vertebrae. They extend from lower border of lamina above to the upper border of the lamina below in the vertebral canal. They are predominantly made up of yellow elastic tissue.

**FIG. 7.17 ■** Intervertebral syndesmosis. Note the location of ligamenta flava (anterior aspect).

The ligamenta flava prevent the separation of laminae in spinal flexion and help to restore the erect posture after flexion thus protecting the disc from the injury.

**Between the adjacent spines :** *Interspinous ligament* connects the adjacent spines and *supraspinous ligaments* connect the tips of spinous processes.

**Between the adjacent transverse processes :** The *intertransverse ligaments* connect the adjacent transverse processes. They are very weak in cervical region and largely replaced by intertransverse muscles.

### Nerve supply of the intervertebral joints

All intervertebral joints are innervated by adjoining spinal nerves, particularly by their posterior divisions.

### **Movements of the cervical spinal column**

Movements of cervical spinal column include:

1. Flexion
2. Extension
3. Lateral flexion
4. Rotation.

**Flexion** is a forward movement whereas **extension** is a backward movement. Both these movements have extensive range of motion.

**Lateral flexion** is the bending of the neck to one or the other side with extensive range of motion.

**Rotation** is a twisting movement with greater degree of freedom.

**Circumduction** is the combination of all the aforementioned movements.

#### **N. B.**

All these movements are enhanced by movements occurring at craniovertebral joints, i.e. atlantoaxial and atlanto-occipital joints.

### **Craniovertebral joints AN 43.1**

These articulations take place between occipital condyles, atlas, and axis ([Fig. 7.18](#) ).

**FIG. 7.18 ■** Posterior view of the ligaments connecting the axis with occipital bone. The superior band of cruciform ligament is cut.

These entire articulations, together act as a universal joint, permitting horizontal and vertical scanning movements of the head, superbly adapted for eye and head coordination.

The craniovertebral joints include:

1. Atlanto-occipital joints
2. Atlanto-axial joints.

### **Atlanto-occipital joints (Fig. 7.18 ) AN 43.1**

These are two atlanto-occipital joints, one on either side between the atlas vertebra and occipital bone.

#### **Type**

These are synovial joints of condyloid (**ellipsoidal**) variety . Here convex condyles of occipital bones are received into elliptical cavities of atlas.

#### **Articular surfaces**

##### **Above**

Convex articular surface of occipital condyles.

## Below

Concave superior articular facets of the atlas (cervical vertebra). They are elongated and kidney shaped with the constrictions in the middle. They are directed medially and forward. Thus, the superior and inferior articular surfaces are reciprocally curved.

## Ligaments

1. **Fibrous capsule (capsular ligament)** : It surrounds the joint and is attached to the margins of the articular surfaces. It is thick posterolaterally and thin posteromedially.
2. Accessory ligaments
  - (a) Anterior atlanto-occipital membrane
    - It is attached below to the anterior arch of the atlas and above to the anterior margin of the foramen magnum.
    - It fuses with the fibrous capsule laterally and is strengthened by cord-like anterior longitudinal ligament anteriorly.
  - (b) Posterior atlanto-occipital membrane
    - It is attached below to the upper border of the posterior arch of the atlas and above to the posterior margin of the foramen magnum. Inferolaterally, it arches over a groove on the upper surface of the posterior arch of atlas for vertebral artery and 1st cervical nerve.

## Arterial supply

By vertebral artery

## Nerve supply

By 1st cervical nerve

## Movements

Because these are ellipsoid joints, the movements are permitted mainly in transverse axes, viz. flexion and extension as in nodding or '*yes movements*'.

## CLINICAL CORRELATION

The **line of gravity of the weight of the head** (approximately 5 kg or 7–11 lbs) passes in front of the atlanto-occipital joints. Therefore, position of head in erect position is maintained by the traction caused by the extensor

muscles, particularly by semispinalis capitis. Thus, semispinalis muscle is responsible for keeping the head in proper position (Fig. 7.6 ).

### Atlanto-axial joints AN 43.1

Three well-separated 3 joints are formed between the atlas and the axis, namely:

1. Median atlanto-axial joint
2. Two lateral atlanto-axial joints.

### N.B.

All these 3 joints function as one unit to produce the movement of rotation of atlas with head around the vertical axis.

### Median atlanto-axial joint (Fig. 7.19 )

#### Type

It is a synovial joint of **pivot variety** . It is formed between the dens of axis and osseoligamentous ring formed by anterior arch and transverse ligament of the atlas.

**FIG. 7.19** ■ Median atlanto-axial articulation.

## Articular surfaces

1. Odontoid process of axis
2. Anterior arch and transverse ligament of atlas

There are two articulations – anterior and posterior – with separate synovial cavities.

*Anteriorly*, the vertically oriented oval facet on the anterior surface of dens articulates with a similar facet on the posterior surface of the anterior arch of the atlas.

*Posteriorly*, the cartilaginous anterior surface of transverse ligament of atlas articulates with the horizontally oriented ovoid facet on the posterior surface of the base of the dens.

## Ligaments

1. **Fibrous capsule** : It is loose and surrounds the anterior joint. It is attached around the margins of the articular facets. It is lined by synovial membrane.
2. **Transverse ligament** : It is attached on each side to the medial surface of the lateral mass of the atlas. In the median plane, its fibres are prolonged: (1) upwards to the basiocciput and (2) downwards to the body of the axis, thus forming the **cruciform ligament of the atlas**. The transverse ligament embraces the narrow neck of the dens and prevents its backward dislocation. A synovial bursa is interposed between the transverse ligament and dens. It is said to be the large posterior part of the median atlanto-axial joint.
3. **Ligaments connecting the axis with the occipital bone**
  - (a) *Apical ligament of the dens* ([Fig. 7.20](#)) extends from tip of odontoid process to the upper surface of the basilar part of the occipital bone near the foramen magnum.

Morphologically, it represents the remnant of the notochord (cf. nucleus pulposus).
  - (b) *Alar ligaments*, one on each side, extend from the upper part of the dens (on side of the tip) to the tubercle on the medial aspect of the occipital condyle. These ligaments are very strong and check excessive rotation and flexion of head. They are, therefore, called *check ligaments*.

- (c) *Membrana tectoria* (Fig. 7.20) is an upward continuation of the posterior longitudinal ligament. It lies posterior to the transverse ligament of the atlas. Inferiorly, it is attached to the posterior surface of the body of the axis and superiorly to the upper surface of the basilar part of the occipital bone above the attachment of upper band of the cruciform ligament.
- (d) Cruciform or cruciate ligament (see transverse ligament).

**FIG. 7.20** ■ Median sagittal section through the foramen magnum and 1st–3rd cervical vertebrae.

### Lateral atlanto-axial joints

These are paired joints, one on each side.

### Type

Synovial joint of **plane variety**.

### Articular surfaces

### Above

Inferior facet of the lateral mass of the atlas. It is flat.

## Below

Superior articular facet of axis. It is also flat; thus, superior and inferior articular facets are reciprocally curved.

## Capsules

It is attached to the margin of articular surfaces. It is supported by anterior longitudinal ligament and ligamentum flavum.

## Movements

These are simultaneous at all the three atlanto-axial joints and consist almost exclusively of rotation of atlas.

In fact, the osseoligamentous ring of atlas rotates around the central pivot formed by the odontoid process. The rotation is limited mainly by alar ligaments. Rotatory movements of atlas with head, around vertical axis, are also called '**No**' movements .

## Summary of atlanto-axial joints

### Summary of atlanto-occipital and atlanto-axial joints

Atlanto-occipital joint ( <b>Fig. 7.21</b> )	Movements and muscles producing them
<ul style="list-style-type: none"><li>• It consists of paired condyloid (ellipsoid) synovial joints, between oval convex condyles of occipital bone and elliptical/oval concave articular surfaces of atlas vertebra.</li><li>• The articular surfaces are oval (elliptical) in shape and reciprocally concavo-convex.</li></ul>	<ul style="list-style-type: none"><li>• <b>Flexion and extension of head (i.e. nodding/'yes' movements)</b> by anterior neck muscles, i.e. longus capitis muscles and posterior neck muscles, i.e. splenius capitis and semispinalis capitis.</li><li>• <i>Limited lateral flexion by rectus capitis lateralis</i></li></ul>
Atlanto-axial joints ( <b>Fig. 7.22</b> )	Movements and muscles producing them

- It is complex joint between atlas and axis vertebrae.
- It consists of three synovial joints:
  - (a) A **pivot-type median atlanto-axial joint** formed between dens of axis and anterior arch of atlas anteriorly and transverse ligament posteriorly.
  - (b) **Two plane-type of lateral atlanto-axial joints** between lateral masses of atlas and axis.
- Rotation of atlas together with head around the dens of axis, which allows to turn head towards right and left side, that is, shaking of head or familiar '**no**' movements .
- The muscles responsible for these movements are sternocleidomastoid, upper trapezius, splenius group of muscles.

**FIG. 7.21 ■** Atlanto-occipital joint.

**FIG. 7.22 ■** Atlanto-axial joint (includes one median atlantoaxial joint and two lateral atlantoaxial joints).

## CLINICAL CORRELATION

- **Hangman's fracture** (Fig. 7.23): It is bilateral fracture of pars interarticularis (area of vertebral arch between superior and inferior articular processes). It is 2nd most common fracture of axis vertebra. It is a **severe extension injury of the neck** that occurs from automobile accident or a fall from height. Because in this injury the vertebral canal is enlarged because of forward displacement of the body of axis, the spinal cord is rarely compressed.  
 This injury is so named because during execution by hanging, the knot of Hangman's rope beneath the chin causes sudden severe extension injury of the neck.  
 Executive hanging can also cause fracture of odontoid process or separation of axis from the 3rd cervical vertebrae.
- **Fracture of odontoid process of axis vertebra.** It is most common odontoid process, and usually occurs because of fall or blow on the head. Excessive mobility of the fractured odontoid process, particularly if associated with rupture of transverse ligament of atlas can cause compression of the spinal cord (Fig. 7.24).

**FIG. 7.23 ■** Hangman's fracture.

**FIG. 7.24 ■** Executive hanging: (A) hanging; (B) fracture of odontoid process; and (C) rupture of transverse ligament of atlas.

**N.B.**

**In executing hanging** , death occurs because of posterior dislocation of

odontoid process (following rupture of transverse ligament of atlas) crushing the lower part of medulla oblongata which houses vital centres and adjoining part of the spinal cord.

## Golden Facts to Remember

• <b>Spinous process of cervical vertebra, which can be readily palpated on the back of the neck</b>	Spinous process of C7 vertebra ( <i>vertebra prominence</i> )
• <b>Cervical vertebra with thickest spinous process</b>	Second cervical (axis) vertebra
• <b>Largest superficial muscle on the back of the neck</b>	Trapezius muscle
• <b>Widest cervical vertebra</b>	1st cervical vertebra
• <b>Thickest cutaneous nerve in the body</b>	Greater occipital nerve (dorsal ramus of C2 spinal nerve)
• <b>Rounded ridge at the side of the median furrow on the back of the neck is produced by</b>	Semispinalis capitis (although it lies deep to trapezius and splenius)
• <b>Intervertebral disc commonly involved in disc prolapse in cervical region</b>	Intervertebral disc between C5/C6 and C6/C7
• <b>Hangman's fracture</b>	Fracture of the pedicles of 2nd cervical (axis) vertebra
• <b>'No' movements occur at</b>	Median atlanto-axial joint of pivot variety
• <b>'Yes' movements occur at</b>	Atlanto-occipital joints of ellipsoid variety
• <b>Dislocation without fracture occurs only in cervical region because</b>	The articular surfaces of articular processes are inclined horizontally
• <b>Suboccipital nerve</b>	Posterior ramus of C1

## CLINICAL CASE STUDY

### Case I

A 59-year-old man visited his family physician and complained that he was suffering from pain on the back of his neck and over the lower part of deltoid region and lateral side of his arm on the right side. Sometimes he also felt tingling and numbness along the lateral aspect of his arm, forearm, and thumb. The X-ray of cervical spine revealed reduced disc space between C4/C5 and C5/C6 vertebrae. The extensive formation of osteophytes (bony spurs) was also seen on the side of bodies of 4th, 5th, and 6th cervical vertebrae. He was told that he was suffering from **cervical spondylosis** .

### Questions

1. What is cervical spondylosis?
2. Mention cause of pain, tingling, and numbness.
3. Name the discs commonly involved in cervical spondylosis.

### Answers

1. Degenerative changes involving intervertebral discs, facet, and uncovertebral joints (refer to page 105 for details).
2. Compression of C5 and C6 nerve roots.
3. Discs between C4/C5 and C5/C6 vertebrae.

### Case II

A 27-year-old boy had raped two minor girls and killed them thereafter. Because this was rarest of rare cases, the judge awarded the capital punishment: **hanging by neck till death** .

### Questions

1. Give the anatomical basis of death in executive hanging.
2. Describe median atlanto-axial joint in brief.
3. Name the ligaments attached to the dens of axis vertebra.
4. What are the parts of cruciform ligament?

### Answers

1. Compression or rupture of the vertebral and carotid arteries leading to cerebral ischaemia. It was earlier thought to be due to dislocation of dens of axis vertebra and rupture of transverse ligament of atlas.
2. See page 105.

3. Apical ligament of dens and alar ligaments.

4. It consists of longitudinal and transverse bands. For details, see page 107.

---

# Chapter 8: Parotid region: Parotid gland and extracranial course of facial nerve

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the parotid gland under the following headings: (a) external features, (b) relations, (c) nerve supply, (d) course of its duct and (e) surgical importance. **AN 28.9**
- Explain anatomical basis of Frey's syndrome. **AN 28.10**
- Enumerate: (a) structures emerging at the periphery of parotid gland, (b) structures present within the parotid gland, and (c) structures pierced by parotid duct.
- Give the anatomical basis of: (a) parotid swellings are very painful, (b) Frey syndrome, and (c) mumps.
- Write short notes on: (a) parotid bed, (b) parotid duct, (c) Patey's faciovenous plane, and (d) extracranial course of facial nerve.

There are three pairs of large salivary glands, namely, **parotid**, **submandibular**, and **sublingual**.

In addition, there are numerous minor salivary glands (approximately 450) located in the mucous lining of tongue, palate, cheeks, and lips. They are called lingual, palatal, buccal, and labial glands, respectively.

The salivary glands produce saliva and pour it directly into oral cavity, which helps in chewing. The saliva also keeps the mouth moist and teeth clean.

The **parotid region** is the area around the ear, bounded *anteriorly* by anterior border of masseter, *superiorly* by the zygomatic arch, *posteriorly* by

mastoid process, and *inferiorly* by line joining the angle of the mandible to the mastoid process.

The principal structures present in this area are **parotid gland** – the *largest salivary gland* and extracranial part of **facial nerve** – the *queen of face* (Fig. 8.1 ).

The facial nerve comes out of the cranial cavity through the stylomastoid foramen in this region and enters the parotid gland, where it divides into five terminal branches which emerge on the face, underneath the anterior margin of the parotid gland (Figs 8.1 and 8.10 ).

**FIG. 8.1 ■** Main features of the parotid region.

The detailed knowledge of the anatomy of parotid region is important in clinical practice particularly while performing surgical procedures on parotid gland.

## **Parotid gland AN 28.9**

The parotid (Gk para = around, otic = ear) gland lies in front of and below the ear. It is the largest of the three pairs of salivary glands, namely, parotid, submandibular, and sublingual. It is composed almost entirely of **serous alveoli** . It is lobulated, yellowish brown, and weighs approximately 25 g.

The parotid gland develops from ectodermal lining of primitive mouth, at

its lateral angle.

## Location

The parotid gland lies in the pyramidal fossa, posterior to the ramus of the mandible called **retromandibular fossa (parotid bed)** .

## Boundaries of the parotid bed (Fig. 8.2 )

It is an irregular in space and bounded:

*Anteriorly*, by the posterior border of the ramus of mandible.

*Posteriorly*, by the mastoid process.

*Superiorly*, by the external acoustic meatus and posterior part of temporomandibular joint.

*Medially*, by styloid process.

**FIG. 8.2** ■ Parotid bed and location of the parotid gland.

The parotid bed is lined by muscles, probably to make it soft as follows:

1. **Ramus** of the mandible is covered by two muscles: masseter laterally and the medial pterygoid medially.
2. **Mastoid process** is covered by two muscles: sternocleidomastoid laterally and posterior belly of digastric muscle medially.

3. **Styloid process** is enveloped by three slender muscles: styloglossus, stylopharyngeus, and stylohyoid.

The parotid gland is too soft to be palpable in healthy individual but one can identify the bony boundaries of the parotid bed.

### Extent

The parotid gland being soft is not confined only to the parotid bed but extends beyond it. The extent of parotid gland is as follows: it extends from external auditory meatus *above*, to the upper part of the carotid triangle *below*; *medially* it extends to the styloid process (close to the side wall of pharynx) and wraps around the neck of the mandible. *Posteriorly*, it overlaps the sternocleidomastoid muscle and *anteriorly* it extends over the masseter for a variable distance.

A part of this forward extension is often detached from the rest of the gland and is known as **accessory parotid gland**. The accessory parotid gland lies between the zygomatic arch above and the parotid duct below (Fig. 8.5). Several ducts from accessory gland open into the parotid duct.

### Parotid capsule (or parotid sheath)

The parotid gland is enclosed in a fibrous capsule called **parotid capsule** (Fig. 8.3).

**FIG. 8.3** ■ Parotid capsule.

It is formed by the tough investing layer of deep cervical fascia. This fascia splits in the region between the angle of the mandible and mastoid process to enclose the gland. The superficial lamina is thick, strong, unyielding, and adherent to the gland, whereas deep lamina is thin. The superficial lamina blends with the epimysium of masseter to form a thick **parotidomasseteric fascia**, which is attached above to the zygomatic arch. The thin deep lamina is attached to the tympanic plate and styloid process of the temporal bone; it thickens to form **stylomandibular ligament**, which separates the parotid gland from the submandibular gland.

### CLINICAL CORRELATION

**Infection of the parotid gland.** The parotid gland is commonly infected by the *mumps virus* causing inflammation and swelling of the gland (**mumps**).

The **parotid swellings are very painful** because of unyielding nature of the parotid capsule, any inflammation or tension within the parotid gland will cause severe pain. This is caused by the stretching of the capsule and stimulation of branches of great auricular nerve.

The pain is usually exacerbated at meal time when gustatory stimulus to gland results in increased parotid secretion enhancing further turgor within the capsule. However, patient is relieved of pain to some extent after taking meals because of release of secretions. This is seen routinely in patients suffering from mumps (also see Clinical Correlation on page 116).

### External features (Figs 8.4 and 8.5 )

The gland resembles a three-sided pyramid with apex directed downwards. It presents the following features:

- **An apex**
- **Four surfaces**
  - (a) Superior surface or base
  - (b) Superficial/lateral surface
  - (c) Anteromedial surface
  - (d) Posteromedial surface
- **Three borders**
  - (a) Anterior
  - (b) Posterior
  - (c) Medial.

**FIG. 8.4 ■** Horizontal section through parotid gland showing its relations and the structures passing through it. The inset figure shows borders and surfaces of the parotid gland. SG, styloglossus muscle; SH, stylohyoid muscle; SP, stylopharyngeus muscle.

**FIG. 8.5** ■ The structures emerging at the periphery of the parotid gland.

## Relations

### Apex

It projects downwards overlapping the posterior belly of digastric muscle and adjoining part of the carotid triangle.

The structures emerging through the apex include (Fig. 8.5 ):

1. Cervical branch of the facial nerve

2. Anterior and posterior divisions of retromandibular vein.

### **Superior surface or base**

It is concave and related to the external acoustic meatus and posterior aspect of temporomandibular joint.

The following structures emerge through it ([Fig. 8.5](#)):

1. Superficial temporal vessels
2. Auriculotemporal nerve.

### **Superficial surface**

It is the largest of the four surfaces. It is covered from superficial to deep by ([Fig. 8.4](#)):

1. Skin
2. Superficial fascia containing anterior branches of greater auricular nerve, superficial parotid (preauricular) lymph nodes, and platysma
3. Parotid fascia
4. Deep parotid lymph nodes embedded in the gland

### **Anteromedial surface**

It is deeply grooved by the posterior border of the ramus of the mandible. It is related to ([Fig. 8.4](#)):

1. Masseter
2. Medial pterygoid
3. Posterior border of the ramus of the mandible
4. Lateral aspect of the temporomandibular joint.

The branches of facial nerve emerge on face from underneath the anterior margin of this surface ([Fig. 8.5](#)).

### **Posteromedial surface**

It is moulded onto the mastoid and styloid processes and their covering muscles. Thus, it is related to ([Fig. 8.4](#)):

1. Mastoid process, sternocleidomastoid, and posterior belly of digastric
2. Styloid process and styloid group of muscles.

The styloid process and its muscles separate the gland from internal carotid artery, internal jugular vein, and last four cranial nerves.

The following structures enter the gland through this surface:

1. Facial nerve trunk in its upper part
2. External carotid artery in its lower part.

### **Anterior border**

It separates the superficial surface from the anteromedial surface. The various structures (from above downwards) emerging in a radiating fashion underneath this border is shown in (Figure 8.5 ):

1. Temporal branch of the facial nerve.	Above the parotid duct
2. Zygomatic branch of the facial nerve.	
3. Transverse facial vessels.	
4. Upper buccal branch of the facial nerve.	
5. <b>Parotid duct.</b>	Below the parotid duct
6. Lower buccal branch of the facial nerve.	
7. Marginal mandibular branch of the facial nerve.	

### **Posterior border**

It separates the superficial surface from the posteromedial surface.

The following structures emerge underneath this border (Fig. 8.5 ):

1. Posterior auricular vessels
2. Posterior auricular branch of the facial nerve.

### **Medial border**

It separates the anteromedial surface from the posteromedial surface. It is related to the lateral wall of the pharynx.

### **Structures present within the parotid gland**

Three main structures, either in part or in whole, traverse the gland and branch within it (Figs 8.4 and 8.6 ). From superficial to deep these are as follows:

1. Facial nerve
2. Retromandibular vein

### 3. External carotid artery.

#### **N.B.**

Some members of the *deep parotid lymph nodes* and *filaments of auriculotemporal nerve* are also located within the gland.

The **facial nerve** (Fig. 8.6 A) is most superficial. It enters the gland through the upper part of the posteromedial surface and divides into its terminal branches within the gland. The branches run horizontally and leave the gland through its anteromedial surface and appear on the face by passing underneath its anterior border.

**FIG. 8.6 ■** The structures traversing the parotid gland: ( **A** ) facial nerve; ( **B** ) retromandibular vein; and ( **C** ) external carotid artery.

The five terminal branches of the facial nerve radiate like a goose-foot through the anterior border of the gland and supply the muscles of facial expression. Such branching pattern of the facial nerve is termed **pes anserinus**.

The **retromandibular vein** (Fig. 8.6 B) occupies the intermediate zone of the gland and is formed by the union of the superficial temporal and maxillary veins. It ends below by dividing into anterior and posterior divisions. The anterior division joins the facial vein to form the **common facial vein**, whereas posterior division joins the posterior auricular vein to form the **external jugular vein**.

The **external carotid artery** (Fig. 8.6 C) pierces the lower part of the posteromedial surface to enter the gland where it occupies the deep zone of the gland. Within the gland, it divides into superficial temporal and maxillary arteries. The transverse facial artery, branch of superficial temporal artery, emerges through the anterior border of the gland.

### **Surgical lobes of parotid gland and Patey's facio-venous plane (Fig. 8.7 )**

The parotid gland is divided into two lobes/parts: **large superficial lobe** and a **small deep lobe**. These lobes are separated from each other by facial nerve and its branches. However they remain connected with each other by the isthmus of the glandular tissue, so that the gland appears H-shaped (shaped like a *collar stud* ) in coronal section.

**FIG. 8.7 ■** Patey's facio-venous (neurovenous) plane in the parotid gland. The retromandibular vein is not shown for clarity. ( **A** ) Two lobes joined by an isthmus; ( **B** ) superficial lobe is removed after dividing on isthmus leaving facial nerve and its branches intact.

The branches of facial nerve pass forward through the isthmus.

The plane between the superficial and deep lobes of parotid gland in which branches of facial nerve and retromandibular vein lie has been designated by **Patey's as facio-venous plane** . This plane helps the surgeons to remove

the parotid tumour (see Clinical Correlation given below), without damaging the nerve.

## CLINICAL CORRELATION

- **Mixed parotid tumour:** It is slow-growing lobulated painless tumour of large superficial part of the parotid gland. It is so called because of its mixed histological appearance. Currently, it is termed as **pleomorphic adenoma**. After many years of slow benign growth, it may undergo a malignant change.
- **Parotidectomy:** A surgical removal of tumour in superficial lobe is called *superficial parotidectomy*, whereas surgical removal of tumour in deep lobe or both in superficial and deep lobes is called *total parotidectomy*.

### Parotid duct (Stenson's duct)

Parotid duct, approximately 5 cm long, emerges from the middle of the anterior border of the gland and opens into the vestibule of the mouth opposite the crown of upper second molar tooth (Fig. 8.8).

**FIG. 8.8** ■ Sites of origin and termination of the parotid duct.

The course taken by the duct is as follows: After emerging from the gland, it runs forward over the masseter between the upper and lower buccal branches of the facial nerve; at the anterior border of masseter, it abruptly turns inwards, almost at 90 degrees (**first bend**) and pierces buccal pad of fat, buccopharyngeal fascia, and buccinator muscle.

After piercing the buccinator muscle, the parotid duct runs forwards (**second bend**) for approximately 1 cm between it and the buccal mucosa. Finally, the duct turns medially (**third bend**) and opens into the vestibule of mouth opposite the crown of upper second molar teeth (Fig. 8.9). This tortuous course of the duct provides a valve-like mechanism to prevent the inflation of the duct system of parotid gland during excessive blowing of the mouth as in trumpet blowing.

**FIG. 8.9** ■ Course of the parotid duct. Also note the structures pierced by it during its course from the parotid gland to the vestibule of the mouth.

### Surface anatomy of the parotid duct

On the face, the parotid duct is represented by the middle third of the line extending from lower border of tragus to the midpoint between the ala of the nose and the red margin of the upper lip.

The accessory gland is drained by a small duct that opens into the upper aspect of the parotid duct.

### CLINICAL CORRELATION

1. The **probing of the parotid duct** is difficult because of its tortuous course. The probe is held at the sharp bends of the duct.
2. The parotid duct lies one-finger breadth below the zygomatic arch, and when the teeth are clenched, it may be rolled up and down against the tense masseter.
3. The parotid duct being a superficial structure on the face, may be damaged in injuries to the face or may be cut inadvertently during surgical procedures on the face.
4. The parotid duct and its ramifications can be demonstrated radiologically by injecting radiopaque dye through a fine needle or cannula inserted into the mouth of the duct in the vestibule of the oral cavity (**parotid sialogram** ).
5. Occasionally, calculi (stones) may form in the parotid gland and parotid duct. The calculi lodged in the distal portion of the gland may be removed by splitting up the duct from its opening in the mouth.

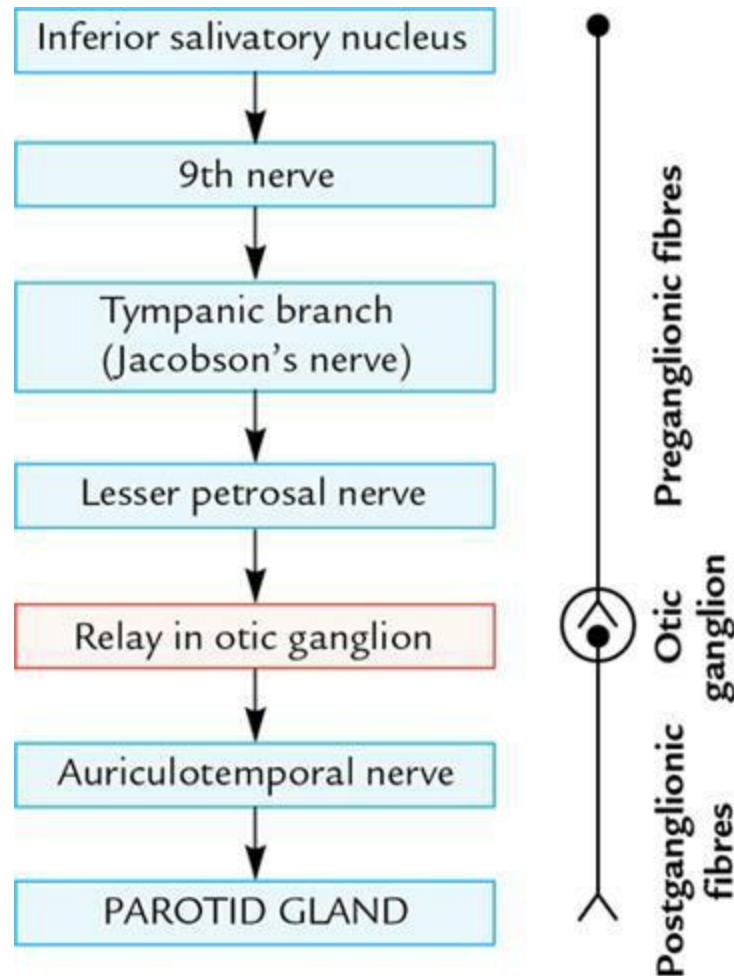

## Nerve supply

The parotid gland is supplied by the parasympathetic, sympathetic, and sensory fibres:

1. **Parasympathetic (secretomotor) supply** ([Fig. 10.12](#) , P137): It is provided through auriculotemporal nerve. The **preganglionic fibres** arise from the inferior salivatory nucleus in the medulla and pass successively through glossopharyngeal nerve, tympanic branch of glossopharyngeal (Jacobson's nerve), tympanic plexus, and lesser petrosal nerve to relay into *otic ganglion* . **Postganglionic fibres** arise from the cells of the ganglion and pass through the auriculotemporal nerve to supply the parotid gland. The stimulation of parasympathetic supply produces watery secretion.
  - The secretomotor supply of parotid gland is shown in [Flowchart 8.1](#)
2. **Sympathetic supply:** It is derived from sympathetic plexus around external carotid artery formed by postganglionic fibres derived from superior cervical sympathetic ganglion. The preganglionic sympathetic fibres arise from the lateral horn of T1 spinal segment. The sympathetic fibres are vasomotor and their stimulation produces thick sticky secretion.
3. **Sensory supply:** It is derived from:

- (a) Auriculotemporal nerve.  
 (b) Great auricular nerve (C2 and C3). The C2 fibres are sensory to the parotid fascia.

**FLOWCHART 8.1** ■ The secretomotor supply of parotid gland.

### **CLINICAL CORRELATION AN 28.10**

**Frey syndrome (auriculotemporal nerve syndrome):** Sometimes penetrating wounds of the parotid gland may *damage auriculotemporal and great auricular nerves* .

The auriculotemporal nerve contains parasympathetic (secretomotor), sensory, and sympathetic fibres.

The great auricular nerve contains sensory and sudomotor fibres.

When these nerves are cut, during regeneration the secretomotor fibres auriculotemporal nerve grow into endoneurial sheaths of fibres of great

auricular nerve supplying cutaneous receptors for pain, touch, and temperature, and sympathetic fibres supplying sweat glands and blood vessels. Thus, a stimulus intended for salivation evokes cutaneous hyperaesthesia, sweating, and flushing. Thus the main cause of this syndrome is aberrant regeneration of the auriculotemporal nerve. *The presenting features of Frey syndrome are as follows:*

- (a) When a person eats, the ipsilateral cheek (parotid region) becomes red, hot, and painful. It is associated with beads of perspiration (gustatory sweating).
- (b) When a person shaves, there is cutaneous hyperesthesia in front of the ear.

### **Vascular supply**

The **arterial supply** of parotid gland is derived from the external carotid and superficial temporal arteries.

The **venous drainage** of parotid gland takes place into retromandibular and external jugular veins.

### **Lymphatic drainage**

The lymphatics from the parotid gland drain into the **superficial and deep parotid lymph nodes**, which in turn drain into **deep cervical lymph nodes**. The *superficial nodes* lie in the superficial fascia over the parotid gland and *deep nodes*, deep to parotid capsule. The majority of lymph nodes (90%) are located close to the surface of gland between capsule and glandular tissue.

### **N.B.**

The parotid gland is the only salivary gland which has two layers of lymph nodes: superficial and deep.

### **Development**

The parotid gland is ectodermal in origin. The parotid primordium develops during the 6th week of intrauterine life as a cord of cells by proliferation of ectodermal lining of the vestibule of the mouth near the angle of primitive oral fissure. It grows backwards towards the ear and branches repeatedly. The parotid bud and its branches canalize to form the duct system and acini. The connective tissue of gland develops from surrounding mesenchyme.

## N.B.

All the salivary glands arise from proliferation of the oral epithelium. Out of the three pairs of large salivary glands, only parotid glands develop from ectoderm, others (submandibular and sublingual) develop from endoderm.

### Facial nerve: Extracranial course AN 28.4

The facial nerve (Fig. 8.10) comes out of cranial cavity through the stylomastoid foramen at the base of the skull, between the styloid and mastoid processes of the temporal bone.

**FIG. 8.10 ■** Extracranial course of the facial nerve. CF, cervicofacial trunk; TF, temporofacial trunk; T, Z, B, MM, and C, represent temporal, zygomatic, buccal, marginal mandibular, and cervical branches of the facial nerve respectively.

After emerging from the foramen, it curves forwards around the lateral

aspect of the root of the styloid process and enters the posteromedial aspect of the parotid gland on the superficial plane. In the gland, it runs superficial to the retromandibular vein for approximately 1 cm and then divides into two trunks: (1) the temporofacial and (2) the cervicofacial. The **temporofacial trunk** runs upwards and subdivides into *temporal* and *zygomatic* terminal branches. The **cervicofacial trunk** passes downwards and forwards, and divides into *buccal*, *marginal mandibular*, and *cervical* terminal branches.

## Branches

Below the base of the skull, the facial nerves give rise to the following branches:

1. **Posterior auricular nerve:** It arises just below the stylomastoid foramen and ascends between the mastoid process and the back of the external acoustic meatus. It supplies occipital belly of occipitofrontalis, auricularis posterior, and auricularis superior (intrinsic muscles of the ear).
2. **Branch to the posterior belly of digastric:** It arises near the origin of the previous nerve and after a very short course supplies the muscle. It also gives a branch to the stylohyoid muscle.
3. **Terminal branches:** These are five in number, namely:
  - (a) *Temporal branch* runs upwards and crosses the zygomatic arch.
  - (b) *Zygomatic branches* run below and parallel to the zygomatic arch.
  - (c) *Buccal branches* are two in number. The upper buccal nerve runs above the parotid duct and the lower buccal nerve runs below the duct.
  - (d) *Marginal mandibular (also called mandibular) branch* runs forwards below the angle of the mandible, deep to the platysma. It then crosses the body of the mandible to supply the muscles of the lower lip and chin.
  - (e) *Cervical branch* runs downwards and forwards to reach the front of the neck, to supply the platysma.
  - (f) The terminal branches supply all the muscles of facial expression (Fig. 3.12, page 58).

## N.B.

- The terminal branches communicate with the sensory branches of the

trigeminal nerve.

- Facial nerve courses through the parotid gland without supplying any structure within it.

## CLINICAL CORRELATION

- **Mumps (viral parotitis):** It is a contagious disease caused by a specific virus called *mumps virus (myxovirus)*. It presents as an acute inflammation and swelling of the gland. There is diffuse enlargement of the parotid gland (parotid swelling) associated with pain and fever. The pain is accentuated by jaw movement as the part of the gland between the external auditory meatus and temporomandibular joint is compressed. The opening of parotid duct becomes swollen and congested. It mostly affects children younger than 15 years. The viral parotitis characteristically does not suppurate. The viraemia associated with mumps can cause complications in the adults such as *epididymo-orchitis*, pancreatitis, or oophoritis.
- **Parotid abscess:** The parotid abscess may occur by spread of infection from the oral cavity. A parotid abscess may spread into parapharyngeal spaces or burst spontaneously on the cheek or into the external auditory meatus.
- **Drainage of the parotid abscess:** A preauricular incision is made in the skin at the root of the auricle and skin flap raised to expose the parotid fascia. The abscess is drained by a blunt horizontal incision in the parotid capsule, parallel to the branches of the facial nerve (*Hilton's method*).
- **Bell's palsy:** The lesion facial nerve in the facial canal just above stylomastoid foramen leads to Bell's palsy leading to facial deformity and awkward facial expression. Hence, facial nerve is also called '*queen of the face*'. It is described in detail on page 58, see also Fig. 3.14.

## Golden Facts to Remember

• <b>Largest salivary gland in the body</b>	Parotid gland
• <b>Commonest cause of parotitis/commonest infection of the parotid gland</b>	Mumps virus

• <b>Queen of face</b>	Facial nerve
• <b>Most common tumour of the parotid gland</b>	Pleomorphic adenoma (mixed parotid tumour)
• <b>Ducts of all major salivary glands open into oral cavity proper except that of</b>	Parotid gland (parotid duct) which opens in the vestibule of the mouth
• <b>Most superficial structure within parotid gland</b>	Facial nerve and its terminal branches
• <b>Deepest structure in the substance of parotid gland</b>	External carotid artery
• <b>Most preferred incision to drain the parotid abscess</b>	Horizontal incision in the parotid fascia (Hilton's method)
• <b>Sensory innervation of skin over parotid gland is provided by</b>	Great auricular nerve
• <b>Only cranial nerve which passes through two foramina of the skull</b>	Facial nerve

## CLINICAL CASE STUDY

A 14-year-old boy presented with a complaint of rapidly growing painful swelling on face in front and below the of ear on the right side. He also told that the pain increases while taking meals but subsides to some extent after finishing the meal. On examination, the physician found that the ear lobule is lifted on the affected side. The examination of oral cavity revealed congestion in mucous membrane of vestibule of mouth opposite the second upper molar tooth on the right side. He was diagnosed as a case of **acute parotitis**.

### Questions

1. What is the commonest cause of acute parotitis?
2. Why are parotid swellings painful?
3. Why does pain increase during meal time and is relieved after taking meals?
4. Name the three structures present within the substance of the parotid gland.

### Answers

1. Mumps (infection of the parotid gland by mumps virus).

2. Because of stretching of tough unyielding parotid capsule which is richly innervated by sensory nerve fibres.
3. Pain increases while taking meal because during mastication, secretion accumulates in the acini because of parasympathetic stimulation, and a part of inflamed gland between temporomandibular joint and external acoustic meatus is compressed. The pain is relieved after meals because pent-up secretion (saliva) within the gland is released during salivation, hence reducing pressure on the parotid capsule.
4. Facial nerve, retromandibular vein, and external carotid artery.

---

# Chapter 9: Submandibular region

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the submandibular gland under the following headings: (a) morphology (location and external features), (b) relations, (c) nerve supply, and (d) applied anatomy. **AN 34.1**
- Describe submandibular ganglion in brief. **AN 34.1**
- Describe the basis of formation of submandibular stones. **AN 34.2**
- Enumerate the relations of posterior belly of digastric muscle.
- Write short notes on: (a) submandibular ganglion, (b) oral diaphragm, (c) hyoglossus muscle, and (d) genioglossus muscle.
- Give the anatomical basis of: (a) swellings of submandibular gland are bimanually palpable, (b) incision to excise the submandibular gland is given 4 cm below the angle of mandible, and (c) ranula.
- Draw the labelled diagrams to show the superficial and deep relations of hyoglossus muscle.
- Describe the origin, insertion, nerve supply, and actions of digastric muscle.

**Submandibular region** is located below and under cover of the body of mandible. It extends upwards up to the mylohyoid line and below up to the hyoid bone. Superficially, it includes both submandibular and submental triangles ([Fig. 9.1](#)).

**FIG. 9.1 ■** Structures seen in the superficial dissection of the right submandibular region.

The deep structures in this region include floor of the mouth and the root of the tongue. Clinically, this region is very important because it is the common site for swellings due to enlargement of submandibular lymph nodes and submandibular salivary gland.

The inflammatory oedema of the floor of the mouth (called **Ludwig angina**) spreads in this region to cause generalized swelling of the region. The surgical procedures are commonly performed in this region; hence, students should study this region very carefully. The term *submandibular* often misleads the students because it gives the impression that the submandibular region deals with the structures below the mandible only. In classical teaching, submandibular region includes only deep structures.

### **Superficial Structures in the Submandibular Region**

The submandibular region is crossed superficially by platysma in the superficial fascia. Deep to platysma, the marginal mandibular nerve crosses the lower border of the mandible near the angle and runs below it across the submandibular region before turning upwards to reach the mental region of the face where it supplies depressors of the lower lip (depressor labii inferioris, depressor anguli oris) and mentalis muscle. The surgical incisions are, therefore, not made along the lower border of the mandible to avoid injury to this nerve. The great auricular nerve crosses the posterior belly of

digastric on its way to supply the skin of face and auricle (Fig. 9.1 ).

### Deep Structures in the Submandibular Region

The deep structures in the submandibular region (also called *contents of the submandibular region* ) are as follows:

1. Suprahyoid muscles (all paired), namely, digastric, stylohyoid, mylohyoid, and geniohyoid
2. Extrinsic muscles of the tongue (all paired), namely, hyoglossus, styloglossus, and genioglossus
3. Submandibular and sublingual salivary glands
4. Facial and lingual arteries
5. Lingual, hypoglossal, and glossopharyngeal nerves
6. Submandibular ganglion.

#### N.B.

It is important to know that on either side of midline, the *submandibular salivary gland* is the most prominent structure and the *hyoglossus muscle* is the key muscle of the submandibular region.

### Muscles of the submandibular region

From the point of view of surgical procedures, muscles in the submandibular region form four muscular planes; from superficial to deep, these are as follows:

1. **First muscular plane:** formed by the digastric and stylohyoid muscles.
2. **Second muscular plane:** formed by the mylohyoid muscle.
3. **Third muscular plane:** formed by the geniohyoid, hyoglossus, and styloglossus muscles.
4. **Fourth muscular plane:** formed by the genioglossus and a part of middle constrictor of the pharynx.

### Muscles of first muscular plane

#### Digastric muscle (Fig. 9.2 )

It is a strap-like muscle consisting of posterior and anterior bellies, united by an intermediate tendon. This muscle is so called because it has two bellies.

**FIG. 9.2 ■** Origin and insertion of the digastric muscle.

## Origin

1. The large *bipennate posterior belly* arises from the mastoid notch of the temporal bone.
2. The small *unipennate anterior belly* arises from the medial surface of digastric fossa on the lower border of the mandible close to the symphysis menti.

## Insertion

1. Posterior belly passes downwards and forwards towards hyoid bone between the carotid triangle below and behind and digastric triangle above and in front. Just above hyoid bones, it pierces stylohyoid muscle and inserted into the intermediate tendon.
2. Anterior belly passes downwards and backwards on the mylohyoid to be inserted into the intermediate tendon.

The *intermediate tendon* is anchored to the junction of the body and greater cornu of hyoid bone by an inverted U-shaped facial sling of investing layer of deep cervical fascia. The tendon of digastric muscle passes between the two slips of tendon of stylohyoid muscle.

## Nerve supply

1. Posterior belly develops from mesoderm of the 2nd pharyngeal arch, and therefore, supplied by the facial nerve.
2. Anterior belly develops from the 1st pharyngeal arch and, therefore, supplied by the mylohyoid nerve, a branch of inferior alveolar nerve from mandibular nerve.

## **Actions**

1. Helps to depress the mandible when the mouth is opened widely against resistance
2. Pulls the hyoid bone upwards during chewing and deglutition.

## **Relations of the posterior belly of digastric muscle**

1. *Superficial relations:*
  - (a) Skin, superficial fascia, platysma, and investing layer of deep cervical fascia
  - (b) Mastoid process and sternocleidomastoid muscle
  - (c) Parotid gland and the angle of the mandible
2. *Deep relations ( [Fig. 9.3](#) ):*
  - (a) Neurovascular bundle of neck consisting of internal jugular vein, external and internal carotid arteries 10th, 11th, and 12th cranial nerves.
3. *Upper border:* Stylohyoid muscle and posterior auricular artery run along the upper border of the posterior belly of the digastric.
4. *Along lower border:* Occipital artery runs along and under the cover of the lower border of digastric.

**FIG. 9.3 ■** Important deep relations of the posterior belly of the digastric muscle.

### **N.B.**

The relations of posterior belly of digastric are important because three cranial nerves: 10th, 11th, and 12th, and three great blood vessels of neck, namely, internal jugular vein, internal, and external carotid arteries pass deep to it.

Differences between the posterior and anterior bellies of the digastric muscles are listed in [Table 9.1](#) .

### **TABLE 9.1**

#### **Differences between posterior and anterior belly of the digastric muscle**

--	--

<b>Posterior belly</b>	<b>Anterior belly</b>
Large	Small
Bipennate	Unipennate
Develops from 2nd pharyngeal arch	1st pharyngeal arch
Supplied by facial nerve (nerve of 2nd pharyngeal arch)	Supplied by mylohyoid nerve (nerve of 1st pharyngeal arch)

### **Stylohyoid muscle (Fig. 9.4 )**

It is a slender muscle that lies along the upper border of the posterior belly of the digastric muscle.

**FIG. 9.4 ■** Origin and insertion of the stylohyoid muscle.

### **Origin**

It arises from the posterior surface of the styloid process.

### **Insertion**

It is inserted into the hyoid bone at the junction between the body and greater cornu. At the insertion, its tendon splits into two slips that pass one on either side of the intermediate tendon of the digastric muscle ([Fig. 9.3](#) ).

### Nerve supply

The stylohyoid muscle develops from the 2nd arch and, therefore, it is supplied by the facial nerve.

### Actions

It draws the hyoid bone upwards and backwards, and elongates the floor of the mouth.

### N.B.

The stylohyoid muscle is considered as the delaminated portion of the posterior belly of the digastric muscle.

## Muscles of second muscular plane

### Mylohyoid muscle ([Fig. 9.5](#) )

It is a flat, triangular muscle lying deep to anterior belly of the digastric muscle. The right and left mylohyoid muscles join in the median fibrous raphe to form the gutter-shaped **floor of the mouth** ; over which lies the tongue; hence, floor of the mouth is also called **diaphragma oris** .

**FIG. 9.5 ■** Origin and insertion of the mylohyoid muscle (as seen from below).

### Origin

From mylohyoid line of the mandible.

### Insertion

The fibres run downwards and medially. The posterior fibres are inserted into the body of the hyoid bone. The middle and anterior fibres are inserted into the median fibrous raphe extending from symphysis menti to the hyoid bone.

### Nerve supply

The mylohyoid muscle develops from the first pharyngeal arch; therefore, it is supplied by mylohyoid nerve, a branch of inferior alveolar nerve from mandibular nerve.

### Actions

1. The mylohyoid muscle elevates the floor of the mouth and hence the

- tongue during the first stage of the deglutition.
2. It also helps in the depression of the mandible against resistance.
  3. It fixes or elevates the hyoid bone.

## **Muscles of third muscular plane**

### **Geniohyoid muscle (Fig. 9.6 )**

It is a narrow muscle that lies alongside the midline deep to the mylohyoid.

**FIG. 9.6 ■** Origin and insertion of the geniohyoid muscle.

### **Origin**

From inferior genial tubercle of the mandible.

### **Insertion**

The fibres run backwards and downwards to be inserted into the anterior surface (front) of the body of the hyoid bone, above the medial part of the mylohyoid muscle.

### **Nerve supply**

C1 fibres through hypoglossal nerve.

## Actions

1. The geniohyoid muscle elevates the hyoid bone by pulling it upwards and forwards and thus shortens the floor of the mouth.
2. They may depress the mandible when the hyoid bone is fixed.

## Hyoglossus muscle (Fig. 9.7 )

It is the flat quadrilateral muscle of the tongue.

**FIG. 9.7** ■ Origin and insertion of the hyoglossus muscle.

## Origin

From upper surface of the entire length of the greater cornu and adjacent part of the body of hyoid bone.

## Insertion

Into the side of tongue between styloglossus laterally and inferior longitudinal medially. The fibres of hyoglossus from hyoid bone run upwards

and slightly forward and decussate with the fibres of styloglossus.

### **N.B.**

A part of hyoglossus may be attached to the lesser cornu of the hyoid bone and forms a separate muscle called *chondroglossus* .

### **Relations**

The hyoglossus, a quadrilateral sheet of muscle, is the key muscle of the suprahyoid region because it serves as a landmark for neighbouring structures in the region. Therefore, its relations are very important to surgeons.

### **Superficial relations (Fig. 9.8 )**

The superficial relations of the hyoglossus muscles are as follows:

1. *Hypoglossal nerve* crosses the lower part of muscle from behind forwards.
2. *Lingual nerve* crosses the upper part of muscle from behind forwards.
3. *Deep part of the submandibular gland* and submandibular duct. The gland lies in the middle of hyoglossus muscle and the duct lies between the gland and the muscle.
4. *Submandibular ganglion* lies between the lingual nerve and deep part of the submandibular gland.
5. *Styloglossus muscle* interdigitates with hyoglossus.
6. *Mylohyoid muscle* overlaps the hyoglossus anterosuperiorly.

**FIG. 9.8 ■ Superficial relations of the hyoglossus muscle.**

### Deep relations (Fig. 9.22 D)

The deep relations of the hyoglossus muscle are as follows:

1. *Inferior longitudinal muscle of tongue*
2. *Genioglossus muscle anteriorly*
3. *Middle constrictor of pharynx posteriorly*
4. *Glossopharyngeal nerve*
5. *Stylohyoid ligament*
6. *Lingual artery* .

### Structures passing deep to posterior border of hyoglossus

From above downwards, these are (Fig. 9.8 ) as follows:

1. *Glossopharyngeal nerve*
2. *Stylohyoid ligament*
3. *Lingual artery* .

### Nerve supply

The hyoglossus muscle develops from **occipital myotomes** , therefore, it is supplied by hypoglossal nerve.

### Actions

1. Depresses the side of tongue to make the dorsal surface of the tongue convex
2. Helps in the retraction of the protruded tongue.

### **Styloglossus muscle (Fig. 9.9 )**

#### **Origin**

From front of the tip of styloid process and adjoining part of stylohyoid ligament.

#### **Insertion**

The fibres run forwards to be inserted into the whole length of the side of tongue, interdigitating with the fibres of the hyoglossus muscle.

#### **Nerve supply**

It is supplied by hypoglossal nerve.

#### **Actions**

Retracts the tongue upwards and backwards, and thus it is antagonist to the genioglossus. Along with its counterpart of opposite side, it forms a median gutter on the dorsum of tongue for the passage of food.

**FIG. 9.9 ■** Origin and insertion of the styloglossus

muscle.

## Muscles of fourth muscular plane

### Genioglossus muscle (Fig. 9.10 )

It is a fan-shaped extrinsic muscle of tongue and along with its counterpart of the opposite side forms the most of the bulk of the tongue.

**FIG. 9.10** ■ Origin and insertion of the genioglossus muscle.

### Origin

From superior genial tubercle of the mandible.

### Insertion

The fibres radiate backwards fan-wise into the substance of the corresponding half of the tongue alongside the median septum, from the tip to the base, for insertion.

1. **Lower fibres** are inserted into the body of the hyoid and form the **root of the tongue**.
2. **Intermediate fibres** pass beneath the anterior border of the

hyoglossus and extend backwards up to stylohyoid ligament and middle constrictor of the pharynx.

3. **Upper fibres** turn upwards and forwards to extend up to the tip of the tongue.

### **Nerve supply**

It is supplied by hypoglossal nerve.

### **Actions**

The muscles of both sides together protrude the tongue and make an elongated gutter on the dorsal surface of the tongue for the passage of food.

## **Nerves of the submandibular region**

### **Lingual nerve**

The lingual nerve arises from posterior division of the mandibular nerve, and descends between the ramus of the mandible and the medial pterygoid muscle. It then inclines forwards and enters the mouth by passing inferior to the lower border of the superior constrictor of the pharynx at its attachment near the posterior end of the mylohyoid line.

Now it enters the submandibular region by passing just behind and inferior to the third molar tooth between medial surface of the mandible and the mucous membrane of the gum ([Fig. 9.11](#) ).

**FIG. 9.11 ■** Features of the internal aspect of the right half of the body of mandible.

In this position, it is liable to be injured by the clumsy extraction of the adjacent tooth, and is accessible to local anaesthetics. In its further course, the lingual nerve lies close to the side of the tongue, crosses the styloglossus and upper part of the hyoglossus, and hooks beneath the submandibular duct. In the process, it crosses the submandibular duct superficially and then turns up deep to the duct (the double crossing).

Attached to the undersurface of the nerve is the submandibular ganglion, which lies on hyoglossus ([Fig. 9.8](#), page 122) just above the deep part of the submandibular gland and supplies to it secretomotor fibres that have synapse in the ganglion. Other postganglionic fibres re-enter the lingual nerve, which transports them to the sublingual gland.

The lingual nerve is itself sensory to the anterior two-third of the tongue and the inner (lingual) surface of the gums, but its content fibres belonging to the chorda tympani nerve carry taste sensations from the anterior two-third

of the tongue except from vallate papillae.

## **Branches**

The lingual nerve gives the following two sets of branches:

1. Branches of communication (communicating twigs), namely
  - (a) Two or more to submandibular ganglion
  - (b) One or two which descend along anterior border of the hyoglossus to unite with the hypoglossal nerve
2. Branches of distribution, namely
  - (a) A gingival branch to the inner surface of the gum
  - (b) Few twigs to the sublingual gland
  - (c) Branches to the anterior two-third of the tongue.

## **Hypoglossal nerve**

The hypoglossal nerve runs forwards, *crosses internal carotid artery, external carotid artery, and loop of lingual* before it enters the submandibular region by passing deep to the posterior belly of the digastric muscle. It continues its course forwards and upwards on the hyoglossus (below the lingual) and then on the genioglossus to enter the tongue. Here it supplies all the muscles of the tongue (intrinsic and extrinsic), except palatoglossus, which is not really a muscle of the tongue.

## **Glossopharyngeal nerve**

The glossopharyngeal nerve before entering the submandibular region descends on the medial side of the stylopharyngeus muscle, curves around its lower border to run forward on its lateral side and supplies it. Then it runs parallel with the lower border of the styloglossus and passes deep to the stylohyoid ligament to disappear underneath the posterior border of the hyoglossus in order to reach the tongue.

Its lingual branches convey both general and taste sensations from the posterior one-third of the tongue.

## **Blood vessels of the submandibular region**

### **Arteries**

The arteries supplying the submandibular regions are as follows:

1. **Facial artery:** The facial artery enters the submandibular region by passing deep to digastric and stylohyoid muscles, turns forwards above these muscles to reach the deep aspect of the angle of the mandible. Now it first hooks around the posterosuperior aspect of the submandibular gland, descends between the lateral surface of the gland and medial pterygoid muscle (Fig. 9.16 ), then hooks around the lower border of the mandible to reach the face. Before hooking around the lower border of the mandible, it gives rise to **submental branch**.
2. **Lingual artery:** The lingual artery after forming a U-shaped loop above the tip of greater cornu of hyoid bone runs forwards deep to the hyoglossus above the hyoid bone and gives rise to two dorsal lingual arteries, which supply **posterior one-third of the tongue and tonsil**.

Then it ascends along the anterior border of hyoglossus and lies on the genioglossus. Here it gives rise to **sublingual artery**, which supplies the **sublingual salivary gland**.

### **N.B.**

Before entering deep to the hyoglossus, it gives off *suprahyoid artery*, which runs along the superior border of the hyoid bone, lateral to the hyoglossus.

### **Veins**

The veins present in the submandibular region are as follows:

1. **Venae comitantes nervi hypoglossi:** These two veins run along the hypoglossal nerve.
2. **Venae comitantes:** These **two veins** accompany the lingual artery and run deep to the hyoglossus muscle.

All of the earlier-mentioned four veins join to form the lingual vein, which drains into the common facial or internal jugular vein.

## **Salivary glands in the submandibular region AN 34.1**

There are two pairs of large salivary glands in the submandibular region. These are submandibular and sublingual salivary glands. The first is located mainly below the floor of the mouth and the latter above the floor of the mouth (Fig. 9.12 ).

**FIG. 9.12 ■** Left submandibular and sublingual salivary glands.

### **Submandibular gland**

The submandibular gland is one of the three pairs of paired salivary glands. This large salivary gland, about the size of a walnut, is situated partly below and partly deep to the posterior half of the mandible. It is half the size of the parotid gland and weighs approximately 10–20 g. It is a mixed type of gland (that is both mucous and serous in nature) but predominantly serous.

### **Parts**

It consists of two parts: (1) a large superficial part and (2) a small deep part. The superficial part lies superficial to the mylohyoid muscle, whereas deep part lies deep to the mylohyoid muscle. The two parts are continuous with each other around the posterior border of the mylohyoid muscle ([Fig. 9.13](#)).

**FIG. 9.13** ■ Schematic horizontal section through submandibular region showing the parts of submandibular gland. The sublingual salivary gland is also seen. Note the relationship of the sublingual gland with the deep part of the submandibular gland and submandibular duct.

### Superficial part

This part of the gland is quite large and fills anterior part of the digastric triangle extending upwards up to the mylohyoid line. The superficial part presents **two ends** – anterior and posterior and **three surfaces** – inferior, lateral, and medial.

The *anterior end* extends up to the anterior belly of the digastric muscle. The *posterior end* extends up to the stylomandibular ligament, which separates the submandibular gland from the parotid gland. This end presents a groove produced by ascending limb of the cervical loop of the facial artery.

### Fascial covering or capsule (Fig. 9.14 )

The superficial part is partially enclosed between the two layers of investing layer of deep cervical fascia. At the greater cornu of hyoid bone, the investing layer of deep cervical fascia splits into two laminae to enclose the superficial part. The superficial layer covers the inferior surface of the gland and is

attached to the base of the mandible. The deep layer covers the medial surface of the gland and is attached to the mylohyoid line of the mandible.

**FIG. 9.14 ■** Capsule of the superficial part of the submandibular gland.

## Relations

The three surfaces of the superficial part of submandibular gland have important relations as follows:

- **Superficial surface** (inferior surface) from superficial to deep is covered by the following structures (Fig. 9.15 ):
  - ◊ Skin
  - ◊ Superficial fascia containing platysma and cervical branch of facial nerve
  - ◊ Deep fascia
  - ◊ Facial vein
  - ◊ Submandibular lymph nodes.
- **Lateral surface** is related to (Fig. 9.16 ):
  - ◊ Submandibular fossa on the inner aspect of the body of mandible

- ◊ Medial pterygoid muscle (near its insertion)
- ◊ Facial artery

It is important to note that the facial artery loops downwards and forwards between the bone and the gland, and then winds around the lower border of the body of the mandible at the anteroinferior angle of the mandible to reach the face (Fig. 9.16 ).

- **Medial surface** is extensive and divided into three parts: anterior, middle, and posterior (Fig. 9.17 ):

(a) *Anterior part* is related to:

- Mylohyoid muscle
- Submental branch of facial artery
- Mylohyoid nerve and vessels

(b) Middle (intermediate) part is related to:

- Hyoglossus muscle
- Styloglossus muscle
- Lingual and hypoglossal nerves
- Submandibular ganglion

(c) *Posterior part* is related to:

- Styloglossus muscle
- Stylohyoid ligament
- Glossopharyngeal nerve
- Wall of pharynx.

**FIG. 9.15** ■ Relations of the superficial (inferior) surface of submandibular salivary gland. The relations of anterior part of the medial (deep) surface are also seen.

**FIG. 9.16** ■ Relations of the lateral surface.

**FIG. 9.17 ■** Relations of the medial (deep) surface of the submandibular gland.

### Deep part

The deep part is small and lies on the hyoglossus muscle deep to the mylohyoid; *posteriorly*, it is continuous with superficial part around the posterior border of the mylohyoid, and *anteriorly*, it extends up to the sublingual salivary gland (Fig. 9.13 ).

### Relations (Fig. 9.18 )

*Medial:* Hyoglossus

*Lateral:* Mylohyoid

*Superior:* Lingual nerve and submandibular ganglion

*Inferior:* Hypoglossal nerve accompanied by a pair of veins (venae comitantes nervi hypoglossi).

**FIG. 9.18 ■** Location and relations of the deep part of submandibular gland and submandibular ganglion. Red circle of broken line represents the superficial part of the submandibular gland.

### **Submandibular duct (Wharton's duct; Fig. 9.19 )**

The submandibular duct is approximately 5 cm long and emerges at the anterior end of the deep part. It runs forwards on the hyoglossus between the lingual and hypoglossal nerves. Near the anterior border of the hyoglossus, it is crossed by lingual nerve. It continues running forward between the sublingual gland and the genioglossus. Here it lies just deep to the mucous membrane of the oral cavity. Finally, it opens into the oral cavity on the summit of a *sublingual papilla* at the side of the frenulum of the tongue (Fig. 13.10 ).

**FIG. 9.19** ■ Submandibular and sublingual ducts.

### Blood supply

The gland is supplied by sublingual and submental arteries and drained by common facial and lingual veins.

### Lymphatic drainage

The lymphatics from submandibular gland first drain into submandibular lymph nodes and subsequently into jugulodigastric lymph nodes.

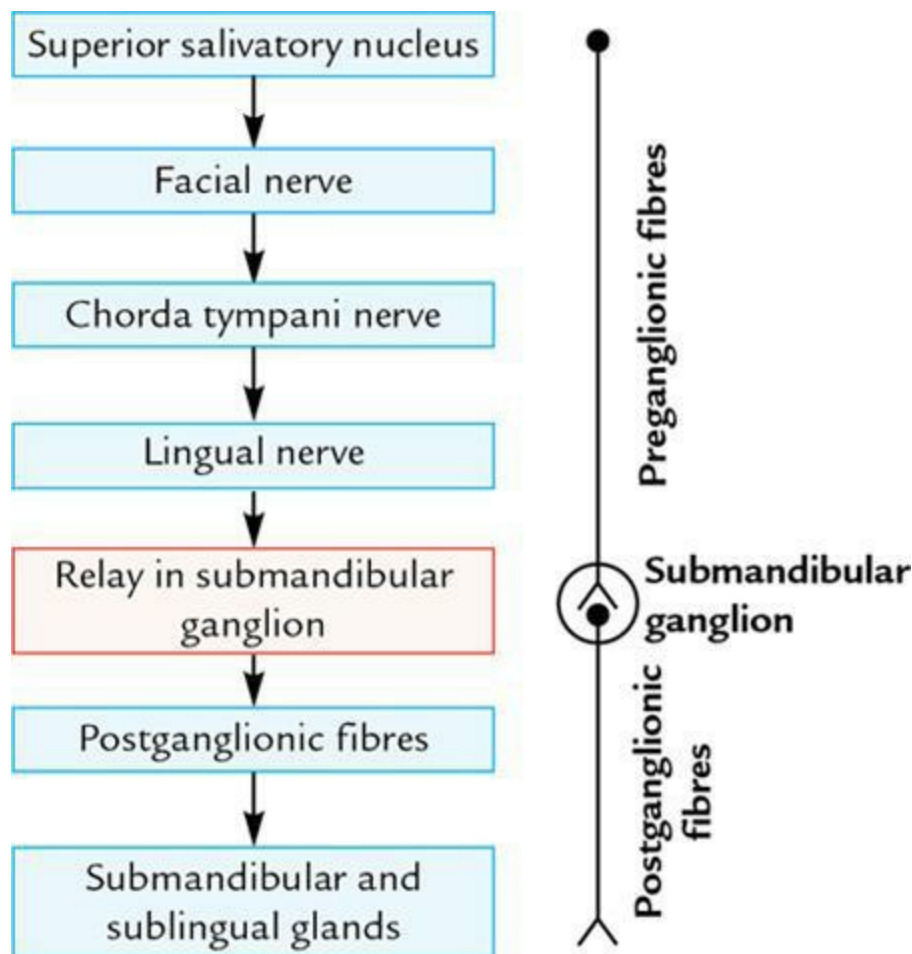

### Nerve supply

The gland is supplied by parasympathetic, sympathetic, and sensory fibres (Fig. 9.21 ):

1. **Parasympathetic (secretomotor) supply** (Flowchart 9.1 ):
  - (a) The preganglionic parasympathetic fibres arise from superior salivatory nucleus in the pons and pass successively through facial, chorda tympani, and lingual nerves; and terminate in the submandibular ganglion, which serves as a relay station.
  - (b) The postganglionic fibres arise from this ganglion and directly supply the submandibular gland.
2. **Sympathetic supply:** The preganglionic fibres arise from T1 spinal

segment and enter the cervical sympathetic trunk to relay in its superior cervical sympathetic ganglion. The postganglionic fibres arise from superior cervical sympathetic ganglion, form plexus around facial artery, and thus reach gland through this artery.

3. **Sensory supply:** The gland gets its sensory supply by the lingual nerve.

**FLOWCHART 9.1 ■** Parasympathetic (secretomotor) supply of submandibular and sublingual glands.

### **N.B.**

Earlier it was thought that only parasympathetic supply is *secretomotor* and sympathetic supply is *vasomotor*. Now it is established without doubt that both parasympathetic and sympathetic supplies are secretomotor. Parasympathetic stimulation produces watery secretion, whereas sympathetic stimulation produces sticky mucus-rich secretion. In addition,

sympathetic supply is vasomotor.

## CLINICAL CORRELATION

- The **formation of calculi in the submandibular gland and its duct** is more common than in the parotid duct for two reasons:
  - ⊕(a) Its secretion is more viscid.
  - ⊕(b) Its duct takes a tortuous and upward course, which hampers its smooth drainage (against gravity) into the floor of the mouth.
- The **excision of the submandibular gland** for calculus or tumour is done by skin incision below the angle of the mandible. Because the *marginal mandibular branch of facial nerve* passes 1 inch posteroinferior to the angle of the mandible before crossing its lower border, the incision, therefore, should be given 4 cm below the angle to avoid injury to this nerve.
- The **swellings of the submandibular gland can be palpated bimanually** by putting an index finger in the mouth and thumb below the angle of the jaw in relation to the position of gland ([Fig. 9.20](#) ) because part of the gland lies in the oral cavity above the floor of the mouth and part outside the oral cavity below the floor of the mouth. The submandibular lymph nodes lying on the surface of the gland cannot be palpated bimanually because they lie below the floor of the mouth (oral diaphragm). Thus, an enlarged submandibular gland can be differentiated from a mass of the submandibular lymph nodes by *bimanual palpation* .
- **Formation of submandibular stones:** The salivary stones are hardened deposits of mineral salts. Of all salivary stones; 80% of them form in submandibular gland. The causes of stone formation are dehydration, inadequate fluid intake, use of diuretics, etc.
  - ⊖ The stone in the submandibular duct can also be palpated manually within the mouth and can even be seen if sufficiently large.
  - ⊖ The stone is removed from within the mouth by incising the mucous membrane and duct over the stone.

**FIG. 9.20** ■ Bimanual palpation of the submandibular salivary gland. (Source: Fig. 6.7, page 295, *Clinical and Surgical Anatomy* , 2e, Vishram Singh. Copyright Elsevier 2007, All rights reserved.)

### **Sublingual gland AN 34.2**

This is smallest of the three pairs of large salivary glands. It lies in the floor of the mouth between the mucous membrane and the mylohyoid muscle. It is almond shaped and rests in the sublingual fossa of the mandible. It is separated from the base of the tongue by the submandibular duct. It is mostly mucus in nature and weighs approximately 3–4 g. The gland pours its secretion by a series of ducts, approximately 15 in number, into the oral cavity on the **sublingual fold** , but a few of them open into the submandibular duct.

### **N.B.**

The gland actually possesses approximately 20 ducts. Most of these ducts (*ducts of Rivinus* ) open separately on the sublingual fold, whereas some ducts from anterior part of the gland unite to form the sublingual duct (*duct of Bartholin*) , which opens into the submandibular duct.

## Nerve supply

It is similar to that of submandibular salivary gland.

## Blood supply

The gland is supplied by the sublingual and submental arteries.

## Lymphatic drainage

The lymphatics from the sublingual gland drain into submental and submandibular lymph nodes.

## CLINICAL CORRELATION

**Ranula:** It is a *large mucus-retention cyst in the floor* of mouth arising from sublingual salivary gland. Sometimes, it may arise from accessory salivary glands, called glands of Blandin and Nuhn, present in the floor of mouth.

The swelling is soft, bluish in colour, and transilluminates. It looks like the belly of frog (*Rana hexadactyla*), hence the name ranula.

## Development of the submandibular and sublingual salivary glands

The submandibular and sublingual glands develop as an outgrowths from the endodermal lining of the floor of the mouth (at alveololingual sulcus).

The submandibular gland arises from a single large bud, whereas sublingual gland arises from a series of small buds, which retain their connection with the floor of the mouth. As a result, the submandibular gland pours its secretion by a single duct and sublingual gland by several ducts in the floor of the mouth.

## N.B.

It is important to remember that the parotid gland develops as an outgrowth of ectodermal lining of the vestibule of the mouth, near its angle.

## Comparison of the three large salivary glands

Comparative features of the three salivary glands are presented in [Table 9.2](#).

## TABLE 9.2

## Comparative features of the parotid, submandibular, and sublingual salivary glands

	<b>Parotid gland</b>	<b>Submandibular gland</b>	<b>Sublingual gland</b>
<b>Location</b>	Below and in front of the ear	Below the mandible	Below the tongue
<b>Development</b>	Ectodermal	Endodermal	Endodermal
<b>Size</b>	Largest (25 g)	Smaller (10–20 g)	Smallest (3–4 g)
<b>Shape</b>	Pyramidal shaped	J-shaped	Almond shaped
<b>Duct and its site of opening in oral cavity</b>	Parotid duct opens into vestibule of oral cavity opposite the second upper molar tooth	Submandibular duct opens into the floor of oral cavity proper on summit of sublingual papilla at the side of frenulum of the tongue	Series of ducts open into the floor of the oral cavity proper on the sublingual fold
<b>Secretomotor nerve supply</b>	<ul style="list-style-type: none"> <li>• Through lesser petrosal nerve</li> <li>• Preganglionic fibres arise from inferior salivatory nucleus</li> <li>• Postganglionic fibres arise from otic ganglion</li> </ul>	<ul style="list-style-type: none"> <li>• Through chorda tympani</li> <li>• Preganglionic fibres arise from superior salivatory nucleus</li> <li>• Postganglionic fibres arise from submandibular ganglion</li> </ul>	<ul style="list-style-type: none"> <li>• Through chorda tympani nerve</li> <li>• Preganglionic fibres arise from superior salivatory nucleus</li> <li>• Postganglionic fibres arise from submandibular ganglion</li> </ul>
<b>Nature of secretion</b>	Serous	Both serous and mucus	Mucus

### **Submandibular ganglion (Langley's ganglion) AN 34.1**

It is a parasympathetic ganglion, which serves as a relay station for secretomotor fibres supplying the submandibular and sublingual salivary glands.

*Topographically* , it is connected to the trigeminal nerve (lingual nerve) but

*functionally* it is related to the facial nerve (through its chorda tympani branch).

## Location

This ganglion is of the size of a pin-head and situated on the outer surface of the hyoglossus muscle. It is suspended from lingual nerve by two twigs. The proximal twig is afferent to the ganglion and distal root is efferent to the ganglion.

## Relations (Fig. 9.18 )

*Above:* Lingual nerve

*Below:* Deep part of the submandibular gland

*Medial:* Hyoglossus muscle

*Lateral:* Submandibular gland (superficial part)

## Roots (Fig. 9.21 )

The submandibular ganglion has three roots, namely: parasympathetic, sympathetic, and sensory.

1. **Parasympathetic root:** It is derived from lingual nerve. The *preganglionic* fibres arise from superior salivatory nucleus situated in pons and pass successively through facial nerve, chorda tympani, and lingual nerves to reach the ganglion where they relay. The *postganglionic* fibres arise from ganglion and directly supply the glands. The parasympathetic fibres provide secretomotor supply to the submandibular and sublingual glands (Fig. 9.21 and Flowchart 9.1 ).
2. **Sympathetic root:** It is derived from sympathetic plexus around the facial artery. The *preganglionic* fibres arise from the first thoracic spinal segment (T1) and enter the cervical sympathetic chain to relay in superior ganglion. The *postganglionic* fibres arise from superior cervical sympathetic ganglion, form plexus around the facial artery to pass through the ganglion without relay and supply the blood vessels in the submandibular and sublingual salivary glands.
3. **Sensory root:** It is derived from lingual nerve.

**FIG. 9.21 ■** Roots and branches of submandibular ganglion.

## Branches

The branches of the submandibular ganglion are as follows:

1. Five to six branches, which supply the submandibular gland.
2. Other fibres join the lingual nerve to supply the sublingual and anterior lingual glands.

## Surgical muscular planes of the submandibular region

During surgery in the submandibular region, the incision is given approximately 4 cm below the mandible.

After giving incision, a surgeon must keep in mind that deep structures in this region are arranged in four muscular planes ([Fig. 9.22](#)). These structures are already described under the section Muscles of the Submandibular Region. However, for an overview and convenience of understanding, these planes are summarized in the following text ([Fig. 9.22](#)).

**FIG. 9.22 ■** Planes of the submandibular region: ( **A** ) first muscular plane; ( **B** ) second muscular plane; ( **C** ) third surgical (muscular) plane; and ( **D** ) fourth surgical (muscular) plane.

### First muscular plane (Fig. 9.22 A)

The major structures in this are: (1) digastric muscle and (2) most of the superficial part of the submandibular gland. The submandibular lymph nodes

lie in close relation to the submandibular gland and are partly hidden under the body of the mandible. Note that superficial part of the submandibular gland partly overlaps both anterior and posterior bellies of the digastric muscle. The facial artery emerges on face by winding around the lower border of the mandible.

### **Second muscular plane (Fig. 9.22 B)**

The major structures in this plane are: (1) mylohyoid muscle and (2) mylohyoid nerve and vessels, which emerge from under cover of the mandible. There is also a large submental branch of the facial artery. The hypoglossal nerve runs horizontally forward on hyoglossus accompanied by venae comitantes nervi hypoglossi.

### **Third muscular plane (Fig. 9.22 C)**

The major structures in this plane are: (1) lingual and hypoglossal nerves, which communicate with each other near the anterior border of hyoglossus; (2) deep part of the submandibular gland and submandibular duct; (3) submandibular ganglion; and (4) styloglossus muscle being crossed superficially by the lingual nerve. Note the double crossing of submandibular duct by lingual nerve. The structures passing deep to posterior border of hyoglossus are also seen.

### **Fourth muscular plane (Fig. 9.22 D)**

The major structures in this plane are genioglossus muscle, middle constrictor of the pharynx and lingual artery, and its branches of distribution are the key features of this plane.

### **Golden Facts to Remember**

• <b>Key muscle of the submandibular region</b>	Hyoglossus
• <b>Smallest of the three pairs of large salivary glands</b>	Sublingual salivary gland
• <b>Wharton's duct</b>	Submandibular duct
• <b>Ducts of Rivinus</b>	Ducts of sublingual salivary gland
• <b>Langley's ganglion</b>	Submandibular ganglion
• <b>Most commonly damaged artery during ligation and surgical</b>	Facial artery

<b>removal of the submandibular gland</b>	
• <b>Most commonly damaged major nerve during surgical removal of submandibular gland</b>	Lingual nerve is (inadvertently) damaged during ligation and division of the submandibular duct

## CLINICAL CASE STUDY

A 35-year-old woman went to her family physician and complained that she felt pain and swelling beneath her right jaw each time she ate a meal. She also told the doctor that pain and swelling more or less completely resolves after taking meal for a time until she takes her next meal, when the same symptoms appear again. On examination, the physician made the following observations:

- Presence of swelling beneath the posterior portion of her right mandible.
- The swelling was bimanually palpable.

He referred the case to ENT surgeon who advised CT scan of the region. CT scan confirmed the presence of a large **stone in the submandibular gland**. He performed a surgery and removed her submandibular gland. After surgery, she noticed a weakness at the corner of her mouth.

## Questions

1. Why is formation of calculus more common in the submandibular gland as compared to the parotid gland?
2. Why is submandibular swelling bimanually palpable?
3. Why did the patient feel weakness at the corner of her mouth after surgery?

## Answers

1. It is because secretion of the submandibular gland is more viscous than that of parotid gland. Secondly, the course of submandibular duct is upwards and tortuous, which hampers the efficient drainage of its secretion (also refer clinical box on page 127).
2. Because it lies on both sides (i.e., above and below) of the floor of the mouth.

3. Because of traction on marginal mandibular branch of the facial nerve.

---

# Chapter 10: Temporal fossa, infratemporal fossa, temporomandibular joint and pterygopalatine fossa

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the boundaries and contents of temporal and infratemporal fossae. **AN 33.1**
- Describe the muscles of mastication under the following headings: origin, insertion, direction of fibres, nerve supply, and actions. **AN 33.2**
- Describe the temporomandibular joint under the following headings: (a) type and articular surfaces, (b) ligaments (c) relations, (d) movements and muscles producing them, and (e) applied anatomy. **AN 33.3**
- Explain clinical significance of pterygoid venous plexus. **AN 33.4**
- Describe the features of dislocation of temporomandibular joint. **AN 33.5**
- Give the anatomical basis of: (a) inferior alveolar nerve block, and (b) referred pain from tongue and teeth.
- Write short notes on: (a) otic ganglion, (b) articular disc of TM joint, (c) mandibular nerve, (d) sphenopalatine ganglion, (e) maxillary nerve, (f) maxillary artery, (g) sphenomandibular ligament, and (h) chorda tympani nerve.

## Temporal fossa (Fig. 10.1 )

The temporal fossa is a slight depression on the side of skull (norma lateralis) between superior temporal line above and zygomatic arch below. It communicates below with infratemporal fossa through a gap deep to the zygomatic arch (Fig 10.1 ).

**FIG. 10.1** ■ Communication (arrows) between infratemporal and temporal fossae.

## Boundaries

*Superiorly:* Superior temporal line

*Inferiorly:* Zygomatic arch

*Anteriorly:* Frontal process of zygomatic bone and zygomatic process of frontal bone

*Posteriorly:* Posterior part of temporal line (which continues anteriorly

with supramastoid crest).

## **Layers of soft tissue**

They are described in detail in [Chapter 3](#) on page 52 and shown in [Figure 3.7](#).

## **Contents**

- *Temporalis muscle*
- *Middle temporal artery* – a branch of superficial temporal artery
- *Zygomaticotemporal nerve*, a branch of maxillary nerve
- *Deep temporal nerves* from anterior division of mandibular nerve
- *Deep temporal arteries* are, a branches of maxillary artery.

The detailed description of contents is as follows:

- *Temporalis muscle*: It is described in detail on page 147.
- *Middle temporal artery*: It is a proximal medial branch of superficial temporal artery. It arises immediately above the zygomatic arch, perforates the temporal fascia to supply temporalis muscle along with deep temporal arteries.
- *Zygomaticotemporal nerve*: It is a branch of maxillary nerve in pterygopalatine fossa, enters the orbit through inferior orbital fissure where it divided into zygomaticotemporal foramen to enter into temporal fossa to provide sensory innervation.
- *Deep temporal nerves*: Anterior and posterior branches of anterior division of mandibular nerve supply temporalis nerve.
- *Deep temporal arteries* (anterior and posterior) arise from 2nd part of maxillary artery. They ascend between temporalis muscle and pericranium to supply overlying temporalis muscle.

## **Infratemporal fossa AN 33.1**

The infratemporal fossa is the space beneath the base of the skull, between the side wall of the pharynx and ramus of the mandible. It communicates with the temporal fossa through a gap deep to the zygomatic arch.

## **Boundaries**

The boundaries of infratemporal fossa ([Fig. 10.2](#)) are as follows:

**Roof:** Formed by the infratemporal surface of the greater wing of the sphenoid. It is pierced by foramen spinosum and foramen ovale.

**Medial wall:** Formed by lateral surface of the lateral pterygoid plate of the sphenoid. It is separated from the anterior wall by pterygomaxillary fissure.

**Lateral wall:** Formed by the ramus of the mandible.

**Anterior wall:** Formed by the infratemporal surface of the maxilla. It is separated from roof by inferior orbital fissure.

**Floor:** Open and extends up to the level of the base of the mandible.

**Posterior wall:** Formed by tympanic plate and styloid process of the temporal bone.

**FIG. 10.2 ■** Boundaries of the infratemporal fossa.

### **Communications (Figs 10.1 , 10.2 and 10.3 )**

The infratemporal fossa communicates:

1. Above with the temporal fossa through a gap, deep to zygomatic arch; and with middle cranial fossa through foramen ovale and foramen spinosum in the infratemporal surface of greater wing of sphenoid.
2. Below it is continuous with the tissue spaces of the neck lateral to the pharynx
3. With the pterygopalatine fossa through pterygomaxillary fissure
4. With the orbit through inferior orbital fissure.

**FIG. 10.3** ■ Schematic diagram to show the boundaries and communications of the infratemporal fossa.

All communications are presented in [Flowchart 10.1](#) .

**FLOWCHART 10.1** ■ Communications of the

infratemporal fossa.

### **N.B.**

The infratemporal fossa can be best visualized as a hollow cube without floor ([Fig. 10.3](#)).

### **Contents**

The major structures present in the infratemporal fossa are as follows:

1. **Muscles:** Lateral pterygoid, medial pterygoid, and tendon of temporalis. They belong to group of muscles called chief muscles of mastication (see page 146).
2. **Blood vessels:** Maxillary artery, maxillary vein, and pterygoid venous plexus
3. **Neural structures:** Mandibular nerve, chorda tympani nerve, and otic ganglion.

## **Muscles of infratemporal fossa AN 33.2**

### **Lateral pterygoid ([Fig. 10.4](#) )**

It is a short, thick conical muscle with its apex pointing backwards. It passes backwards and slightly laterally from the roof and medial wall of the fossa to the neck of the mandible.

**FIG. 10.4 ■** Origin and insertion of the lateral pterygoid muscle.

### Origin

The lateral pterygoid consists of two heads, upper and lower:

1. The **upper smaller head** arises from the infratemporal surface and crest of the greater wing of the sphenoid bone.
2. The **lower larger head** arises from the lateral surface of the lateral pterygoid plate of the sphenoid bone.

### Insertion

The fibres of two heads run backwards and laterally, and converge to form a thick tendon, which is inserted into:

1. Pterygoid fovea on the front of the neck of the mandible

2. Articular disc and capsule of the temporomandibular joint (TMJ).

### Nerve supply

Lateral pterygoid is supplied by a branch of anterior division of the mandibular nerve.

### Actions

1. Lateral pterygoids of two sides depress the mandible (opens the mouth) by pulling forward the condylar processes of the mandible and the articular discs of the TMJs.
2. Lateral and medial pterygoid muscles of two sides acting together protrude the mandible.
3. Lateral and medial pterygoid muscles of the two sides contract alternately to produce side-to-side movements of the lower jaw as in chewing.

### N.B.

- The lower head of lateral pterygoid passes between the two heads of the medial pterygoid muscle.
- It is the only masticatory muscle, which opens the mouth.
- The articular disc of temporomandibular joint is developmentally a part of tendon of lateral pterygoid muscle.

### Relations (Fig. 10.5 )

The lateral pterygoid is regarded as the **key muscle of the infratemporal region** because its relations provide a fair idea about the layout of structures in this region. Its relations are as follows:

#### *Superficial:*

1. Ramus of the mandible
2. Masseter
3. Tendon of temporalis
4. Superficial head of medial pterygoid
5. Maxillary artery and its temporal and masseteric branches

#### *Deep:*

1. Mandibular nerve
2. Middle meningeal artery

3. Sphenomandibular ligament
4. Deep head of medial pterygoid muscle

*Structures emerging at the upper border:*

1. Deep temporal nerves (two in number)
2. Masseteric nerve

*Structures emerging at the lower border:*

1. Inferior alveolar nerve and artery
2. Lingual nerve
3. Middle meningeal artery (it passes up deep to the lower border)

*Structures passing through the gap between the two heads:*

1. *Maxillary artery* , which enters the gap to reach the pterygopalatine fossa through pterygomaxillary fissure.
2. *Buccal nerve* , a branch of mandibular nerve. It comes out through the gap to provide sensory innervation to the skin and mucous membrane of the cheek.

**FIG. 10.5 ■** Relation of the lateral pterygoid muscle.

### **Medial pterygoid (Fig. 10.6 )**

The medial pterygoid is a thick quadrilateral muscle and consists of two heads: superficial and deep.

**FIG. 10.6 ■** Origin and insertion of the medial pterygoid muscle.

### Origin

1. The small **superficial head** (a small slip of muscle) arises from maxillary tuberosity and lateral surface of the pyramidal process of palatine bone.
2. The **large deep head** (forming the bulk of muscle) arises from medial surface of the lateral pterygoid plate and grooved surface of the pyramidal process of palatine bone.

### Insertion

The fibres run downwards, backwards, and laterally to be inserted by a strong tendinous lamina into a roughened area on the posteroinferior part of the medial surface and angle of ramus of mandible as high as the mandibular foramen and as forwards as the mylohyoid groove ([Fig. 9.11](#) ).

### Nerve supply

The medial pterygoid is supplied by a *nerve to medial pterygoid* , a branch from the main trunk of the mandibular nerve.

## Relations

*Superficial* (Fig. 10.7):

1. Lingual nerve
2. Inferior alveolar nerve
3. Inferior alveolar vessels.

*Deep:*

1. Levator palati and tensor palati muscles
2. Superior constrictor of pharynx
3. Styloglossus and stylopharyngeus muscles

**FIG. 10.7** ■ Superficial relations of the medial pterygoid muscle.

## Actions

1. Medial pterygoids of two sides elevate the mandible to help in closing

- of mouth.
2. Acting with lateral pterygoids, the medial pterygoids protrude the mandible.
  3. When medial and lateral pterygoids of one side act together, corresponding side of the mandible is rotated forwards and to the opposite side.
  4. Lateral and medial pterygoids of two sides when contract alternately produce side-to-side movements, which are used to grind the food.

## Blood vessels of infratemporal fossa

### Maxillary artery (Figs 10.7 and 10.8 )

The maxillary artery is the larger terminal branch of the external carotid artery.

**FIG. 10.8 ■** Branches of the maxillary artery. L, lingual branch.

It arises behind the neck of the mandible, runs horizontally forward up to the lower border of lower head of lateral pterygoid. Now it turns upwards and forwards, crosses the lower head of lateral pterygoid superficially (sometimes deep). After emerging between the two heads of lateral pterygoid, it enters the

pterygopalatine fossa by passing through pterygomaxillary fissure. Here, it ends by giving its terminal branches.

The maxillary artery has a wide territory of distribution. It supplies:

- (a) Upper and lower jaws
- (b) Muscles of temporal and infratemporal fossae
- (c) Nose and paranasal sinuses
- (d) Palate and roof of pharynx
- (e) External and middle ear
- (f) Pharyngotympanic tube
- (g) Dura mater.

### **N. B.**

The maxillary artery enters the infratemporal fossa by passing forwards, between the neck of mandible and the sphenomandibular ligament.

### **Parts and relations**

For description purposes, maxillary artery is divided into *three parts* by the lower head of lateral pterygoid muscle. The parts are as follows:

1. **First part (mandibular part):** From beginning (origin) to lower border of lateral pterygoid. It lies between the neck of the mandible laterally and sphenomandibular ligament medially. The auriculotemporal nerve lies above this part.
2. **Second part (pterygoid part):** From lower border to the upper border of the lower head of lateral pterygoid (i.e., second part lies on or deep to lower head of lateral pterygoid).
3. **Third part (pterygopalatine part):** From upper border of the lower head of lateral pterygoid to pterygopalatine fossa. In pterygopalatine fossa, it lies in front of the pterygopalatine ganglion.

### **Branches of the maxillary artery (Fig. 10.8 )**

#### **I. Branches from the first part (five branches)**

1. **Deep auricular artery** passes upwards and backwards to enter the external acoustic meatus by piercing its floor and supplies:
  - (a) Skin of external acoustic meatus
  - (b) Outer surfaces of tympanic membrane.

2. **Anterior tympanic artery** enters the tympanic cavity by passing through petrotympanic fissure and it supplies the **inner surface of the tympanic membrane**.
  3. **Middle meningeal artery** is the largest meningeal branch. It supplies **meninges** as well as the **skull bone**.
    - Clinically, it is the most important branch of the maxillary artery.
    - The middle meningeal artery* arises from the first part of the maxillary artery. It ascends upwards deep to the lateral pterygoid, behind the mandibular nerve. Passing between the two roots of the auriculotemporal nerve to enter the cranial cavity through foramen spinosum in company with meningeal branch of mandibular nerve (nervus spinosus).
    - As it emerges in the cranial cavity, it courses laterally on the floor of the middle cranial fossa and turns upwards and forwards on the greater wing of the sphenoid, where it divides into frontal and parietal branches:
      - (a) *Frontal (anterior) branch*, courses up towards the pterion and then curves backwards to ascend towards the vertex, lying over the precentral gyrus of the cerebral hemisphere. In the region of pterion, the artery frequently lies in a bony tunnel in the parietal bone for a centimetre or more.
      - (b) *Parietal (posterior) branches* arch backwards on the squamous part of the temporal bone, cross the lower border of the parietal bone in front of its mastoid angle; here it divides into branches, which spread out as far as lambda. It lies along the superior temporal gyrus.
- Distribution:* The middle meningeal artery and its branches lie outside the dura and deep to the inner surface of the skull in the extradural space. Both of these are supplied by the artery.

### **N.B.**

The middle meningeal artery and its branches are accompanied by corresponding veins, which lie between the artery and the bone.

4. **Accessory meningeal artery** runs upwards and enters the cranial cavity through foramen ovale.
  - It supplies **meninges** and structures in the **infratemporal fossa**.
5. **Inferior alveolar/dental artery** runs downwards between the sphenomandibular ligament and the ramus of the mandible, enters

the mandibular foramen, runs through the mandibular canal, supplies molar and premolar teeth and adjoining gum. It then divides into mental and incisive branches.

◦The incisive branch supplies the **canine and incisor teeth**. The mental artery emerges through the mental foramen to supply the **skin of the chin**. Before entering the mandibular foramen, the inferior alveolar artery gives off two branches, namely:

- (a) *Lingual branch*: accompanies the lingual nerve and supplies the **mucous membrane of the cheek**.
- (b) *Mylohyoid branch*: pierces the lower end of the sphenomandibular ligament, passes downwards and forwards to run in the mylohyoid groove. It supplies the **mylohyoid muscle**.

## II. Branches from the second part (four branches)

1. **Deep temporal arteries (usually two in number)** ascend up on the lateral aspect of the skull deep to the temporalis muscle, which they supply.
2. **Pterygoid branches** supply the medial and lateral pterygoid muscles.
3. **Masseteric artery** passes laterally through the mandibular notch and supplies the masseter muscle from its deep surface.
4. **Buccal artery** supplies buccinator muscle.

## III. Branches from the third part (six branches)

1. **Posterior superior alveolar artery** arises from maxillary artery just before it enters the pterygomaxillary fissure. It divides into two or three branches, which enter the foramina on the posterior surface of the body of maxilla, run into alveolar canals, and supply the molar and premolar teeth and mucous membrane of maxillary air sinus.
2. **Infraorbital artery** also arises from maxillary artery just before it reaches the pterygopalatine fossa. The artery passes successively through inferior orbital fissure, infraorbital groove, and infraorbital canal, and appears on the face through the infraorbital foramen. It gives the following branches:
  - In the orbit*:
    - (a) Branches to orbital contents.

(b) Middle superior alveolar artery to premolar teeth.

(c) **Anterior superior alveolar artery**, which descends through canaliculus sinuosus in the anterior wall of the maxillary sinus. It supplies the maxillary air sinus and canine and incisor teeth of the upper jaw.

◦*In the face:* It gives off branches to supply the lacrimal sac, medial angle of the eye, side of nose and upper lip.

3. **Greater palatine artery** passes downwards in the greater palatine canal and appears in the oral cavity at the posterolateral corner of the hard palate through the greater palatine foramen. Now it runs forwards in the groove along the alveolar arch to the incisive fossa where it enters the lateral incisive canal to enter the nasal cavity. It supplies the roof of the mouth and adjoining gum, whereas in the greater palatine canal, the artery gives off lesser palatine arteries that emerge through foramina of the same name and supply the soft palate and tonsil.
4. **Pharyngeal artery** passes backwards through the palatovaginal canal and supplies the mucous membrane of the nasopharynx, auditory tube, and the sphenoidal air sinus.
5. **Artery of pterygoid canal** runs backwards in the pterygoid canal and supplies the pharynx, auditory tube and the tympanic cavity.
6. **Sphenopalatine artery** is considered as the continuation of the maxillary artery. It is the most important branch of the third part of the maxillary artery. It enters the nasal cavity in the posterior part of the superior meatus through sphenopalatine foramen. Here it divides into:

(a) Posterior lateral nasal

(b) Posterior septal branches.

¶The posterior lateral nasal branches supply the lateral wall of the nose and sphenoidal and ethmoidal air sinuses, the posterior septal branches cross the undersurface of the body of the sphenoid and then pass forwards and downwards along the nasal septum. One of the branches of this group is long, runs in a groove on the vomer towards the incisive canal and anastomoses with the terminal branch of the greater palatine artery.

¶The branches of maxillary artery are summarized in [Table 10.1](#)

## N.B.

- Most of the branches from the first and second parts of maxillary artery accompany the branches of the mandibular nerve.
- Branches from the third part of the maxillary artery accompany the branches of maxillary nerve and pterygopalatine ganglion.
- Branches from the second part of the maxillary artery are muscular only and supply muscles of mastication.
- All the branches (1st and 3rd part) of the maxillary artery pass through bony foramina and fissures except branches from its second part.

## TABLE 10.1

### Branches of the maxillary artery

	First part	Second part	Third part
Branches	Five	Four	Six
1	Deep auricular artery	Deep temporal artery	Posterior superior alveolar (dental) artery
2	Anterior tympanic artery	Pterygoid branches	Infraorbital artery
3	Middle meningeal artery	Masseteric artery	Greater palatine artery
4	Accessory meningeal artery	Buccal artery	Pharyngeal artery
5	Inferior alveolar artery		Artery of pterygoid canal
6			Sphenopalatine artery

### Maxillary vein

It is a short venous trunk, which accompanies the first part of the maxillary artery. It is formed by the confluence of veins from the *pterygoid venous plexus* and passes backwards between the sphenomandibular ligament and the neck of the mandible. Within the parotid gland, it unites with the superficial temporal vein to form the retromandibular vein.

## Pterygoid venous plexus AN 33.4

It is a network of very small veins that lie around and within the lateral pterygoid muscle.

### Tributaries:

- They correspond to branches of maxillary artery, i.e. sphenopalatine, deep temporal, pterygoid, and buccal.

### Communications:

- The pterygoid venous plexus communicates:
  - (a) With inferior ophthalmic vein via inferior orbital fissure
  - (b) With cavernous sinus by emissary veins via foramen ovale or foramen of Vesalius
  - (c) With facial vein through the deep facial vein.

The plexus is drained by maxillary vein which is formed at the lower border of the lateral pterygoid muscle.

## CLINICAL CORRELATIONS

**Pterygoid plexus is clinically important** because it:

- Provides a route of infection from dangerous area of face and teeth to the cranial cavity into the cavernous sinus, through emissary veins
- Is potential site of haematoma when inadvertently penetrated by needle during *posterior-superior alveolar nerve block*.
- Is sometimes referred to as a **peripheral heart** for during yawning in the morning when the mouth is widely open because of contraction of lateral pterygoid muscle, the stagnant venous blood in pterygoid plexus is pumped up into the cavernous sinus and maxillary vein. Possibly this is the reason why people yawn in the morning when they get up from sleep.

## Neural structures in infratemporal fossa

The infratemporal fossa contains the mandibular nerve and its branches, chorda tympani nerve, and otic ganglion.

### Mandibular nerve (Fig. 10.9 )

The mandibular nerve is the largest of the three divisions of the trigeminal nerve. It is a mixed nerve, consisting of both sensory and motor fibres. It is a

nerve of the first pharyngeal arch, hence supplies all the structures derived from this arch, for example, muscles of mastication.

**FIG. 10.9 ■** Course and distribution of the mandibular nerve. SM, submandibular ganglion.

### Course and relations

It begins in the middle cranial fossa as two roots: a larger sensory root and a smaller motor root. The **large sensory root** arises from lateral convex part of the trigeminal ganglion and immediately leaves the cranial cavity by passing through foramen ovale to enter the infratemporal fossa. The **small motor root** arises from the pons, and lies deep to the trigeminal ganglion and the sensory root. It also passes through foramen ovale to join the sensory root just below the foramen ovale in the infratemporal fossa, thus forming the main trunk. The mandibular nerve trunk is short and after a short course divides into a small anterior and large posterior division.

### *Relations of trunk of mandibular nerve in the infratemporal Fossa*

*Medial:* Tensor palati muscle and otic ganglion

*Lateral:* Upper head of lateral pterygoid muscle

*Posterior:* Middle meningeal artery

*Anterior:* Posterior border of lateral pterygoid plate.

## Branches

### From the main trunk

Two branches arise from the main trunk, a sensory branch (nervus spinosus) and a motor branch (nerve to medial pterygoid):

1. **Nervus spinosus (meningeal branch):** It takes a recurrent course to enter the cranial cavity through foramen spinosum with middle meningeal artery and supplies the dura mater of the middle cranial fossa.
2. **Nerve to medial pterygoid:** It arises from the medial aspect of the main trunk, close to the otic ganglion traverses through the ganglion (without synapsing) and supplies the medial pterygoid from its deep aspect. In addition to medial pterygoid, it also supplies tensor veli palatini and tensor tympani muscles.

### From anterior division

The anterior division is mainly motor and gives branches to all muscles of mastication except medial pterygoid, which is supplied by nerve to medial pterygoid from the main trunk. The branches from the anterior divisions are as follows:

1. **Masseteric nerve:** It emerges at the upper border of the lateral pterygoid, just in front of the TMJ, passes laterally through the mandibular notch, along with masseteric artery to supply the masseter from its deeper aspect. It also supplies to the TMJ.
2. **Deep temporal nerves:** These are usually two in number, anterior and posterior. The anterior and posterior deep temporal nerves emerge at the upper border of the lateral pterygoid and ascend up in the temporal fossa to supply the temporalis muscle from its deep aspect.
3. **Nerve to lateral pterygoid:** It runs with the buccal nerve and enters the deep surfaces of both the heads of lateral pterygoid muscle, which it supplies.
4. **Buccal nerve:** It contains all the sensory fibres of the anterior

division. It emerges between the two heads of the lateral pterygoid and courses downwards and forwards onto the buccinator muscle, giving branches to the skin of the cheek. It then pierces the buccinator muscle and supplies the mucous membrane of the cheek and gum of the lower jaw opposite the molars and second premolar teeth.

### **N.B.**

All the branches of anterior division of the mandibular nerve are motor except buccal nerve which is sensory.

### **From posterior division**

The posterior division is mainly sensory. It gives the following three branches:

1. **Auriculotemporal nerve:** This nerve arises by two roots, which after encircling the middle meningeal artery unite to form the single trunk. It runs backwards between the neck of the mandible and the sphenomandibular ligament. Behind the neck of the mandible, it turns upwards and ascends over the root of zygoma to enter the temple behind the superficial temporal vessels.
  - Distribution :*
    - (a) Its *auricular branches* supply skin of the tragus, upper part of the pinna, external auditory meatus and tympanic membrane. The lower parts of these regions are supplied by great auricular nerve and auricular branch of the vagus nerve.
    - (b) Its *articular branches* supply the TMJ.
    - (c) Its *superficial temporal branches* supply the skin of the temple.
    - (d) It also supplies *secretomotor fibres* to the parotid gland.
2. **Lingual nerve:** It is the smaller terminal branch of posterior division of the mandibular nerve. It is sensory to the mucous membrane of anterior two-third of the tongue *except vallate papillae*.
  - Course and relations:* It begins approximately 1 cm below the skull. It runs first between tensor veli palatini and lateral pterygoid and then between lateral and medial pterygoids. Approximately 2 cm below the skull, it is joined by the chorda tympani nerve. After emerging at the lower border of the lateral pterygoid, it first runs downwards and forwards between the ramus of the mandible and

medial pterygoid, comes in direct contact with the mandible where the bone is thinned to form a shallow groove below and medial to the last molar tooth, just above the posterior end of the mylohyoid line. This groove separates the attachments of pterygomandibular raphe above and mylohyoid muscle below. It enters the mouth on the superior surface of the mylohyoid, and then it crosses the styloglossus to reach the lateral surface of the hyoglossus. Finally, it lies on the surface of the genioglossus. Here it winds round the submandibular duct (first above, then lateral, then below and finally medial to the duct) and divides into its terminal branches.

◦*Distribution:*

- (a) Provides sensory supply to floor of mouth, lingual surface of the gum and anterior two-third of the tongue
- (b) Carries preganglionic secretomotor fibres to submandibular and sublingual salivary glands.

3. **Inferior alveolar nerve:** It is the larger terminal branch of the posterior division of mandibular nerve. It is a mixed nerve. It receives all the motor fibres of the trigeminal nerve.

◦*Course:* It emerges below the lower head of the lateral pterygoid and passes vertically downwards and forward on the medial pterygoid. The nerve lies anterior to inferior alveolar vessels between the sphenomandibular ligament and the ramus of the mandible. Then enters the mandibular foramen in company with inferior alveolar artery, traverses the mandibular canal as far as mental foramen, where it terminates by dividing into mental and incisive branches.

◦*Branches:*

- (a) *Nerve to mylohyoid* arises from the inferior alveolar nerve before it enters the mandibular canal. It pierces the sphenomandibular ligament to reach the mylohyoid groove. It supplies mylohyoid and anterior belly of digastric muscle.
- (b) *Dental branches* supply molar and premolar teeth.
- (c) *Mental nerve* emerges out through mental foramen to supply skin of the chin and skin and mucous membrane of the lower lip.
- (d) *Incisive branch* supplies canine and incisor teeth.

The branches of the mandibular nerve are summarized in [Table 10.2](#) .

 **TABLE 10.2**

### Branches of the mandibular nerve

From main trunk	From anterior division	From posterior division
• Nervus spinosus (meningeal branch)	• Masseteric nerve	• Auriculotemporal nerve
• Nerve to medial pterygoid	• Deep temporal nerves	• Lingual nerve
	• Nerve to lateral pterygoid	• Inferior alveolar nerve
	• Buccal nerve	

#### N.B.

All the branches of posterior division of the mandibular nerve are sensory except *nerve to mylohyoid* , which is motor.

#### CLINICAL CORRELATION

- **Inferior alveolar nerve block (generally called inferior alveolar block or IA block):** It is the most common nerve block performed in dentistry to carry out dental procedures on the mandibular teeth.  
The anaesthetic agent is injected slightly superior to the entry of inferior alveolar nerve into the mandibular foramen being overhung by the lingula. While performing the inferior alveolar nerve block, if needle is inserted too far posteriorly, it may enter the parotid gland and damage the facial nerve leading to *transient facial palsy*.
- The lingual nerve is at great risk (10%) during surgical removal of the impacted third molar tooth. The nerve is also at risk during surgical removal of the submandibular salivary gland, during which the submandibular duct must be dissected out carefully from the nerve.
- **Referred pain:** It is the pain frequently referred from one branch of mandibular nerve to the other. Thus, in patients suffering from tongue cancer, the pain radiates to the ear and to the temporal fossa in the area

of distribution of auriculotemporal nerve. The pain is relieved by dividing the lingual nerve below and behind the last molar tooth. At this site, the nerve is in contact with the mandible and covered only by mucous membrane. Similarly, pain from teeth is also referred to the ear and temporal region.

### **Chorda tympani nerve (Figs 10.10 , 10.11 )**

The chorda tympani nerve is the slender branch of facial nerve. It is so named because of its intimate relationship to the middle ear (tympanum).

### **Functional components (Fig. 10.10 )**

The chorda tympani nerve contains:

- 1 *General visceral efferent fibres*: These are preganglionic parasympathetic (secretomotor) fibres to submandibular and sublingual salivary glands.
- 2 *Special visceral afferent fibres*: These fibres carry taste sensations from anterior two-third of tongue (except vallate papillae).

**FIG. 10.10 ■** Functional components of the chorda tympani nerve.

### **Origin, course, and relations (Fig. 10.11 )**

It arises from facial nerve in the facial canal approximately 6 mm above the stylomastoid foramen, within the posterior wall of the tympanic (middle ear)

cavity. It enters the middle ear through the posterior canaliculus of chorda tympani in the posterior wall, runs across the lateral wall (tympanic membrane). Here it crosses medial aspect of handle of malleus and lateral aspect of long process of incus. At the anterior margin of tympanic membrane, it enters anterior canaliculus in the anterior wall of the middle ear, passes through canaliculus and emerges at the base of skull through medial end of petrotympanic fissure. It then goes medially, forwards and downwards, grooves the medial side of the spine of the sphenoid, running anteroinferiorly deep to lateral pterygoid to join the posterior aspect of the lingual nerve approximately 2 cm below the base of the skull.

**FIG. 10.11** ■ Origin, course, and relations of the chorda tympani nerve.

## Distribution

1. It supplies secretomotor fibres to submandibular and sublingual glands through the submandibular ganglion.
2. It carries taste sensations from anterior two-third of the tongue (except vallate papillae).

## Otic ganglion (Fig. 10.12 )

It is a small parasympathetic ganglion connected to the mandibular division of trigeminal nerve and provides a relay station to the secretomotor fibres to

the parotid gland. Topographically, it is intimately related to the mandibular nerve but functionally it is related to glossopharyngeal nerve.

**FIG. 10.12** ■ Otic ganglion and its connections.

### Size

Pinhead (2–3 mm in size).

### Location

Infratemporal fossa, just below the foramen ovale.

### Relations

*Lateral:* Mandibular nerve

*Medial:* Tensor palati muscle.

*Posterior:* Middle meningeal artery

*Anterior:* Medial pterygoid muscle.

### Roots or connections

1. **Parasympathetic motor (secretomotor):** From lesser petrosal nerve.
  - *Preganglionic parasympathetic fibres* arise from inferior salivatory nucleus; pass successively through glossopharyngeal nerve, tympanic branch of glossopharyngeal nerve (Jacobson's nerve), tympanic plexus, and lesser petrosal nerve to relay in the ganglion. *Postganglionic parasympathetic fibres* from ganglion cells pass through auriculotemporal nerve to supply parotid gland.
2. **Sympathetic:** From sympathetic plexus around the middle meningeal artery.
  - *Preganglionic sympathetic fibres* arise from T1 and T2 spinal segments, enter the cervical sympathetic chain at the level of its inferior ganglion and then ascend to relay in the superior cervical sympathetic ganglion. The postganglionic fibres arise from this ganglion and form plexus around the middle meningeal artery. They then pass through the ganglion without relay to reach the parotid gland via auriculotemporal nerve. They are vasomotor in nature and responsible for thick salivary secretion.
3. **Sensory:** From auriculotemporal nerve.
4. **Somatic motor:** Nerve to medial pterygoid. It passes through ganglion to supply medial pterygoid, tensor palati, and tensor tympani muscles.

## Branches

<ol style="list-style-type: none"> <li>1. Postganglionic parasympathetic</li> <li>2. Postganglionic sympathetic</li> <li>3. Sensory</li> </ol>	All supply parotid gland through auriculotemporal nerve
--	---

## N.B.

- In humans, the *chorda tympani nerve* is connected to the otic ganglion and *nerve to pterygoid canal*. These connections provide an alternative pathway of taste sensations from anterior two-third of the tongue.
- Clinical evidence suggests that in humans the parotid gland also receives

secretomotor fibres through chorda tympani nerve.

## Temporomandibular joint AN 33.3

It is a bilateral synovial articulation between the temporal bones of skull and mandible below. It acts as a sliding hinge between the skull and mandible. They allow the movements of the mandible for speech and mastication.

The mandible is a single bone having two heads, which articulate on each side with temporal bone of cranium. The cranium, with which the mandible articulates, is also, mechanically a single component. The movement cannot take place at one TMJ without a concomitant movement occurring at the joint on the opposite side. Therefore, TMJs are the bilateral components of a single **craniomandibular articulation/joint**. The TMJs are often involved in various disease processes such as bruxism (teeth grinding), osteoarthritis, subluxation, dislocation, etc.

**Type:** Bicondylar synovial joints of ellipsoid variety.

### Articular surfaces

The **upper articular surface** is formed from behind forwards by the:

(1) *glenoid fossa (temporal fossa) fossa* and (2) *articular eminence* of the temporal bone. This surface is concavo-convex from behind forwards ([Fig. 10.13](#) ).

The **lower articular surface** is formed by the head (condyle) of the mandible. This surface is elliptical and convex.

The articular surfaces are **covered by fibrocartilage** and not by hyaline cartilage ([Fig. 10.13](#) ).

The fibrocartilage is less susceptible to degeneration and has a greater repair capacity.

**FIG. 10.13** ■ Articular surfaces of the temporomandibular joint.

### Unique features of temporomandibular joint

- Two joints together act as a single unit – the **craniomandibular joint**.
- It is *complex joint* because of presence of an *intra-articular disc*.
- It is *atypical joints* because the articular surfaces are covered by fibrocartilage.

### Fibrous capsule

It is a fibrous sac which encloses the joint cavity. It is attached above to the articular tubercle, the circumference of articular fossa, and the squamotympanic fissure; and below to the neck of mandible.

The capsule is loose above the intra-articular disc and tight below it.

The synovial membrane lines the inner aspect of the fibrous capsule and the neck of the mandible.

### Joint cavity (Figs 10.13 and 10.14 )

The cavity of TMJ is completely divided into *upper meniscotemporal* and *lower meniscomandibular compartments* by an intra-articular disc of fibrocartilage.

The upper compartment permits *gliding movements*, whereas lower

compartment permits *gliding as well as rotational movements* .

### Articular disc

The articular disc is an oval plate of fibrocartilage. Though termed *fibrocartilage* , it consists mainly of collagen fibres with few cartilage cells.

It is congruent with both the articular surfaces. Thus, its upper surface is concavo-convex (from before backwards) and its inferior surface is concave. The concavo-convex superior surface fits against the articular eminence and the concavity of the articular fossa. The lower concave surface fits with convex head of the mandible.

The periphery of the disc is attached firmly to the fibrous capsule.

The disc has a thick margin, the *peripheral annulus* and a central depression on its inferior surface. In sagittal section, the disc appears to possess a thin *intermediate zone* and thickened anterior and posterior bands (Fig. 10.14 ). The anterior band extends anteriorly through the capsule to be continuous with the tendon of lateral pterygoid. The posterior band splits into two laminae: upper and lower. The upper lamina composed of fibroelastic tissue is attached to the squamotympanic fissure. The lower lamina, composed of fibrous nonelastic tissue, is attached to the back of the condyle. The bilaminar region contains a venous plexus. The central part of the disc is avascular.

**FIG. 10.14** ■ Parts of the intra-articular disc.

The elastic fibres in the posterior part of the disc bring back the disc in the articular fossa when the open mouth is closed.

### **Parts of articular disc (Fig. 10.14 )**

In sagittal section, the articular disc of TMJ presents five different parts, from before backwards these are: (1) **anterior extension** , (2) **anterior thick band** , (3) **intermediate zone** , (4) **posterior thick band**, and (5) **posterior bilaminar zone** .

### **Ligaments**

The ligaments are lateral temporomandibular, sphenomandibular, and stylomandibular ligaments. The latter two are accessory ligaments (Fig. 10.15 A and B).

1. **Lateral temporomandibular ligament:** It is a true ligament and formed as a result of thickening on the lateral aspect of the capsular ligament. Its fibres are directed downwards and backwards. It is attached above to the articular tubercle on the root of zygoma and below to the posterolateral aspect of the neck of the mandible. The lateral ligament strengthens the lateral aspect of the capsule.
2. **Sphenomandibular ligament:** It is attached above to the spine of the sphenoid and below to the lingula and lower margin of the mandibular foramen of the mandible. It lies on a deeper plane away from the joint capsule. The sphenomandibular ligament represents the unossified intermediate part of the sheath of the Meckel's cartilage of the first pharyngeal arch. It becomes accentuated and taut when the mandible is protruded.

◦ **Relations of sphenomandibular ligament (Fig. 10.16 A and B) are as follows:**

- ↳ **Laterally**, it is related to: (1) lateral pterygoid muscle, (2) auriculotemporal nerve, (3) maxillary artery, and (4) inferior alveolar nerve and vessels.
- ↳ **Medially**, it is related to: (1) chorda tympani nerve, (2) wall of the pharynx and (3) medial pterygoid.

**FIG. 10.15 ■** Ligaments of the temporomandibular joint: ( **A** ) fibrous capsule and lateral ligament; and ( **B** ) accessory ligaments.

**FIG. 10.16 ■** Relations of the sphenomandibular ligament: ( **A** ) lateral relations and ( **B** ) medial relations. It also shows medial relations of temporomandibular joint as seen in coronal section.

### N.B.

Near its lower end, the sphenomandibular ligament is pierced by *mylohyoid nerve and vessels* .

### CLINICAL CORRELATION

The sphenomandibular ligament is an important landmark for administration of local anaesthetic during *inferior alveolar nerve block* .

3. **Stylomandibular ligament:** It is attached above to the lateral surface of the styloid process and below to the angle and adjoining posterior border of the ramus of the mandible.
  - The stylomandibular ligament is formed because of thickening of

the investing layer of deep cervical fascia, which separates the parotid and submandibular glands.

This ligament also becomes taut when the mandible is protruded.

### N.B.

The **accessory ligaments of temporomandibular joints** limit the range of motion (ROM) of TMJs preventing it from coming in contact with the tympanic plate behind and from passing ahead of articular eminences/tubercles in front. With mandible, they form a **children 'swing'** (Fig. 10.17 ).

**FIG. 10.17** ■ 'Swing' formed by the mandible and accessory ligaments of TMJs.

## Relations

### *Lateral:*

- (a) Skin and fasciae
  - (b) Parotid gland
  - (c) Temporal branch of the facial nerve
- Note, laterally the joint is subcutaneous.

*Medial* (Fig. 10.16 B):

- (a) Tympanic plate separating it from internal carotid artery
- (b) Spine of sphenoid
- (c) Auriculotemporal nerve (roots)
- (d) Middle meningeal artery
- (e) Sphenomandibular ligament
- (f) Chorda tympani nerve

*Anterior/in front:*

- (a) Tendon of lateral pterygoid
- (b) Masseteric nerve and vessels

*Posterior/behind:*

- (a) Postglenoid part of parotid gland separating it from external auditory meatus
- (b) Superficial temporal vessels
- (c) Auriculotemporal nerve
- (d) External acoustic meatus

*Above:*

- Floor of middle cranial fossa separated by a thin plate of bone.

## **Nerve supply**

1. *Auriculotemporal nerve*: Its articular twigs enter the joint from its posterior aspect.
2. *Masseteric nerve*: Its articular twigs enter the joint from its anterior aspect.

## **Blood supply**

1. Maxillary artery
2. Superficial temporal artery

The articular twigs of these arteries enter the posterior aspect of the capsule.

## **Lymphatic drainage**

The lymph from TMJ is drained into:

1. Superficial parotid (preauricular) nodes
2. Deep parotid nodes
3. Upper deep cervical nodes.

## Stability

The joint is much more stable when the mouth is closed (i.e., when the teeth are in occlusion) than when the mouth is open. In occlusion, the teeth themselves stabilize the mandible on maxilla and no strain is thrown on the joints when an upward blow is received on the mandible. Further in the occluded position, the forward movement of condyle is discouraged by the articular eminence and by the contraction of the posterior fibres of the temporalis muscle, whereas the backward movement of the condyle is prevented by the lateral ligament and the contraction of the lateral pterygoid muscle.

## Movements of the mandible

When the TMJ of two sides is in *position of rest*, a small free space exists between the upper and lower teeth but lips are in contact. The various movements of mandible occur in this position.

The lower jaw can be depressed, elevated, protruded, retracted, and moved from side to side, by movements at TMJs.

## Mechanism

All of the above-mentioned movements of lower jaw involve two basic movements, which occur at TMJ, of course with the help of muscles:

1. Gliding movement
2. Rotational movement.

The *upper meniscotemporal compartment* of TMJ permits gliding movements, during protraction (protrusion), retraction, and chewing.

The *lower meniscotemporal compartment* permits rotation around two axes: (1) a transverse axis, during depression and elevation and (2) a vertical axis during side-to-side/chewing movements.

With these two types of movements, gliding and rotation, and with right and left TMJs working together, most of the movements of the lower jaw can be accomplished perfectly as desired. These include opening and closing the jaws and shifting the lower jaw to one side ([Fig. 10.18](#) ).

**FIG. 10.18** ■ Movements of the lower jaw related to temporomandibular joint to show the opening and closing of the mouth. Note the changing relation of the condyle of the mandible.

The movements occurring at the TMJs are as follows:

1. Depression
2. Elevation
3. Protraction
4. Retraction
5. Side-to-side (chewing) movements.

1. **Depression (lowering jaw to open mouth):** During depression, the head of mandible along with the articular disc glides forward in the upper meniscotemporal compartment on both the sides by the contraction of lateral pterygoid muscle. At the same time, head rotates forward underneath the articular disc by the contraction of suprahyoid

muscles, namely, digastric geniohyoid and mylohyoid. The gravity also helps in opening the mouth.

2. **Elevation (elevating jaw to close the mouth):** During elevation, the movements take place in a reverse order to that of depression, i.e., first the head of mandible along with the articular disc glide backward in the upper meniscotemporal compartment by temporalis, masseter, and medial pterygoid, and then head rotates backward on the lower surface of the disc by posterior fibres of temporalis.
3. **Protrusion/protraction:** During this movement, mandibular teeth move forward in front of maxillary teeth. In this act, head of mandible along with articular disc glide forwards in the upper meniscotemporal compartment on both sides by simultaneous action of medial and lateral pterygoids of both sides.
4. **Retraction:** During this movement, the head of mandible along with articular disc glide backwards in the upper meniscotemporal compartment by the contraction of the posterior fibres of temporalis muscle and bring the joint in the resting position. The forceful retraction is assisted by deep fibres of masseter, digastric, and geniohyoid muscles. At the end of this movement, the head of the mandible comes to lie underneath the articular tubercle.
5. **Side-to-side (chewing) movements:** These movements occur alternately in the right and left TMJs. In chewing movements, the head of the mandible on one side glides forwards along with the disc (as in protraction), but the head of the mandible on the opposite side merely rotates on the vertical axis. As a result, the chin moves forwards and to one side, i.e., towards the side on which no gliding has taken place.

During this movement, the medial and lateral pterygoids of one side contract alternatively with those of opposite side.

The alternate movements of this kind on the two sides result in side-to-side movements of the lower jaw.

## **Muscles producing movements**

### **Depression (opening of mouth)**

It is produced mainly by lateral pterygoid helped by gravity. The digastric, geniohyoid, and mylohyoid muscles help when the mouth is opened widely or against resistance.

### Elevation (closing the mouth)

It is caused by medial pterygoid, masseter, and temporalis (vertical fibres).

### N.B.

Closing the mouth is stronger action than the opening the mouth. Therefore, when attacked by a street dog, it is advisable to keep the mouth of dog closed, if possible.

### Protraction

It is done by lateral and medial pterygoids and masseter.

### Retraction

It is done by posterior fibres of temporalis. It may be assisted by middle and deep fibres of the masseter, the digastric, and geniohyoid muscles.

### Side-to-side (chewing) movements

These movements are performed by alternate contraction of medial and lateral pterygoids on each side.

Movements of the TMJ and muscles producing them are summarized in [Table 10.3](#).

 **TABLE 10.3**

### Movements of the mandible and muscles producing them at TMJ

Movement	Muscle	
<b>Depression</b>	<b>Lateral pterygoid</b> Digastric Geniohyoid Mylohyoid Gravity	
<b>Elevation</b>	Masseter Medial pterygoid Temporalis	
<b>Protrusion (protraction)</b>	Medial pterygoid Lateral pterygoid	of both sides
<b>Retraction</b>	Posterior fibres of temporalis	

**Side-to-side (chewing) movement**

Medial and lateral pterygoids of each side contracting alternatively

## CLINICAL CORRELATION

- **Palpation of the temporomandibular joint and associated muscles:** The bilateral palpation is must to assess the entire joint and its associated muscles. First, the patient is asked to open and close the mouth several times. Then he or she is asked to move the opened jaw to left, and to right, and finally he or she is asked to move the jaw forward. For digital palpation of condyle of moving mandible, a finger is placed into the outer portion of the external auditory meatus.
- **Dislocation of the mandible ( Fig. 10.19 ) AN 33.5 :** The mandible is dislocated anteriorly. When the mouth is widely open, mandibular condyles move forward and lie underneath the articular eminences. This is the most unstable position of the temporomandibular joints. In this position, if there is excessive opening of mouth as during yawning, sudden violence or convulsive spasm of lateral pterygoid muscles, the heads of mandible may slip anteriorly and get locked into the infratemporal fossa deep to zygomatic arch; as a result, the mouth remains open and cannot be closed anymore. Any passive effort to do that will invariably fracture the neck of the mandible on one or both sides.
  - ◊ To reduce dislocation, the condyle must be lowered and pushed back behind the summit of articular eminence into the articular fossa. Thus, the reduction is done by depressing the jaw with thumb placed on the last molar teeth, and simultaneously elevating the chin.

## N.B.

Bilateral mandibular dislocation is most common but unilateral dislocation with jaw deviating to the opposite side can also occur.

- **Temporomandibular joint syndrome:** This syndrome consists of group of symptoms arising from temporomandibular joints and their associated masticatory muscles. The typical presenting symptoms are as follows:
  - ◊ *Diffuse facial pain* due to spasm of masseter muscle
  - ◊ *Headache* due to spasm of temporalis muscle
  - ◊ *Jaw pain* due to spasm of lateral pterygoid.

These symptoms may be associated with clicking and pain in the joint. The clicking is often audible when the patient is chewing. It occurs when the posterior attachment of the disc becomes stretched or detached, allowing the disc to become temporarily or permanently trapped anteriorly. The derangement of articular disc results from an overclosure or malocclusion.

- During surgery of temporomandibular joints, the facial nerve should be preserved with utmost care.

**FIG. 10.19** ■ Temporomandibular joint: ( **A** ) normal and ( **B** ) in anterior dislocation.

## Muscles of mastication AN 33.2

The muscles of mastication are group of muscles concerned with movements of mandible at the TMJs during mastication (Fig. 10.20 ).

**FIG. 10.20** ■ Muscles of mastication producing movements of the temporomandibular joint. The *arrows* indicate the direction of their actions. Chief muscles of mastication are labelled in bold.

These are:

1. Temporalis
2. Masseter
3. Lateral pterygoid
4. Medial pterygoid

The temporalis muscle is situated in the temporal fossa, the masseter muscle on the outer aspect of mandibular ramus, while medial and lateral

pterygoids lie in the infratemporal fossa.

### **N.B.**

#### **Accessory muscles of mastication. These are:**

- (a) Buccinator
- (b) Digastric
- (c) Mylohyoid
- (d) Geniohyoid.

*The characteristic features of the principal muscles of mastication are as follows:*

1. All are located in and around the infratemporal fossa.
2. All are inserted into the ramus of the mandible.
3. All are innervated by the mandibular division of the trigeminal nerve.
4. All are concerned with movements of the mandible on the TMJs.
5. All develop from mesoderm of the first pharyngeal arch.

The buccinator puts the bolus of food between teeth of upper and lower jaws for grinding; and prevents accumulation of food in the vestibule of mouth while other muscles help in depression of mandible when hyoid bone is fixed by infrahyoid muscles. Therefore buccinator is the most important accessory muscle of mastication.

#### **Temporalis (Fig. 10.21 )**

It is a fan-shaped muscle located in the temporal fossa. It is covered by tough temporal fascia which is attached above to the temporal line and below to the zygomatic arch.

**FIG. 10.21 ■** Origin and insertion of the temporalis muscle.

## Origin

It arises from:

1. Whole of the floor of temporal fossa except the part formed by the zygomatic bone.
2. Deep surface of the temporal fascia.

## Insertion

The fibres converge and descend to form a tendon, which passes through the gap between the zygomatic arch and the side of the skull. The muscle is inserted into:

1. The medial surface, apex, anterior, border of the coronoid process of ramus of mandible.
2. The anterior border of the ramus of mandible, almost up to the last molar tooth.

### **N.B.**

The temporalis muscle is fan shaped. The anterior fibres are oriented vertically, the posterior-most fibres are disposed almost horizontally, and intervening intermediate fibres are placed obliquely.

### **Nerve supply**

The temporalis is supplied by *anterior and posterior deep temporal nerves*, the branches of the anterior division of the mandibular nerve.

### **Actions**

The temporalis muscle **elevates the mandible** and so closes the mouth and approximates the teeth. This movement requires both the upward pull of the anterior fibres and backward pull of the posterior fibres.

**Posterior fibres** retract the mandible after it has been protruded.

### **Masseter (Fig. 10.22 )**

The masseter (Greek: masseter = a chewer) is a thick quadrilateral muscle covering the lateral surface of the ramus of the mandible including its coronoid process. The condylar process is left uncovered.

**FIG. 10.22 ■** Origin and insertion of the masseter muscle.

## Origin

The masseter consists of the following three layers:

1. Superficial layer
2. Middle layer
3. Deep layer.

**Superficial layer** is largest of the three layers of masseter and arises by a thick aponeurosis from maxillary process of zygomatic bone and anterior two-third of the inferior border of the zygomatic arch.

**Middle layer** arises from lower border of the posterior one-third of the zygomatic arch.

**Deep layer** arises from deep surface of the zygomatic arch.

# Insertion

1. **Superficial fibres** pass downwards and backwards at 45 degrees to be inserted into the angle and lower posterior half of the lateral surface of the ramus of the mandible.
2. **Middle fibres** pass vertically downwards to insert into the central part of the ramus.
3. **Deep fibres** pass vertically downwards to insert into the upper part of the mandibular ramus and its coronoid process.

## N.B.

- Intramuscular tendinous septa in the superficial layer are responsible for producing ridges on the ramus of the mandible.
- Middle and deep fibres together constitute the deep part of the masseter.

# Nerve supply

The masseter is supplied by a **masseteric nerve**, a branch from anterior division of the mandibular nerve.

# Actions

The masseter muscle **elevates the mandible** to close the mouth.

# Lateral pterygoid

It is described on pages 133–134.

# Medial pterygoid

It is described on page 134.

The origin, insertion, nerve supply, and actions of chief muscles of mastication are summarized in [Table 10.4](#) .

 **TABLE 10.4**

### CLINICAL CORRELATION AN 43.5

**Clinical testing of muscles mastication:** The muscles of mastication and their motor innervation can be tested clinically by asking the patient to clench his or her teeth repeatedly and then palpating the temporalis and masseter in the temporal fossa and over the ramus of mandible, respectively.

## Pterygopalatine fossa

The pterygopalatine fossa is a pyramidal space situated deeply below the apex of the orbit, between the pterygoid process of sphenoid behind and the perpendicular plate of palatine in front. More laterally, back of maxilla replaces palatine bone as anterior boundary of the entrance of the fossa – the pterygomaxillary fissure.

### Boundaries (Fig. 10.23 )

*Anterior:* Perpendicular plate of the palatine and posterior surface of the maxilla (superomedial part).

*Posterior:* Pterygoid process and adjoining part of anterior surface of the greater wing of the sphenoid.

*Medial:* Upper part of the perpendicular plate of palatine orbital and sphenoidal process of the palatine.

*Lateral:* The fossa opens into the infratemporal fossa through pterygomaxillary fissure.

*Superior:* Undersurface of the body of the sphenoid and orbital process of the palatine. The lateral part of the roof is open and here fossa opens into the orbit through inferior orbital fissure.

*Inferior:* Pyramidal process of the palatine bone in the angle between the maxilla and the pterygoid process.

**FIG. 10.23** ■ Boundaries of the pterygopalatine fossa.

## Communications

*Anteriorly:* With the orbit through the medial end of the inferior orbital fissure.

*Posteriorly:*

1. With the middle cranial fossa through foramen rotundum.
2. With the foramen lacerum through the pterygoid canal.
3. With the pharynx through palatovaginal canal.

*Medially:* With the nose through sphenopalatine foramen.

*Laterally:* With the infratemporal fossa through pterygomaxillary fissure.

*Inferiorly:* With the oral cavity through greater and lesser palatine canals.

## Contents

The following are the main contents of the pterygopalatine fossa:

1. Maxillary nerve
2. Pterygopalatine ganglion
3. Third part of the maxillary artery.

### Maxillary nerve (Fig. 10.24 )

The maxillary nerve, the second division (V<sub>2</sub>) of the trigeminal nerve is purely sensory.

**FIG. 10.24** ■ Origin, course, and branches of the maxillary nerve.

### Course and relations

It arises from the convex anterior border of the trigeminal ganglion, pierces the trigeminal cave of dura to reach the lower part of the lateral wall of the cavernous sinus. The nerve leaves the middle cranial fossa through foramen rotundum to reach the pterygopalatine fossa. It traverses straight in the upper part of the fossa and enters the orbit through inferior orbital fissure; hence, it is called *infraorbital nerve*. The infraorbital nerve (in fact a continuation of maxillary nerve) runs forward along the floor of the orbit in the infraorbital

groove and canal in succession and appears on the face, through infraorbital foramen. Therefore, in its course, the maxillary nerve traverses four regions in succession: the middle cranial fossa, the pterygopalatine fossa, the orbit, and the face.

### **N.B.**

In the pterygopalatine fossa, the pterygopalatine ganglion is suspended from the maxillary nerve by two roots.

### **Branches and distribution**

The maxillary nerve gives off the following branches:

#### **A. In the middle cranial fossa**

1. **Meningeal branch**, which supplies the dura mater of the middle cranial fossa.

#### **B. In the pterygopalatine fossa**

1. **Ganglionic (communicating) branches**, two in number to pterygopalatine ganglion.
2. **Zygomatic nerve** enters the orbit through inferior orbital fissure and divides on the lateral wall of the orbit into:
  - (a) A zygomaticotemporal branch, which passes through a foramen in the zygomatic bone to supply the skin of the temple
  - (b) A zygomaticofacial branch, which passes through the foramen in the zygomatic bone to supply the skin of the face
3. **Posterior-superior alveolar nerve** enters one or two foramina on the posterior surface of the body of maxilla and supplies the mucous membrane of the maxillary air sinus. Then it breaks up to form superior dental plexus, which supplies the molar teeth and adjoining part of the gum.

#### **C. In the orbit (infraorbital canal)**

1. **Middle-superior alveolar nerve** passes downward and forward along the lateral wall of the maxillary sinus, joins superior dental plexus and supplies the premolar teeth.
2. **Anterior-superior alveolar nerve** runs in the anterior wall of the

maxillary sinus through a bony canal called *canalis sinuosus* and divides into dental and nasal branches:

- (a) The dental branches join the superior dental plexus and supply the canine and incisor teeth.
- (b) The nasal branches appear in the lateral wall of the inferior meatus and supply the mucous membrane of the lateral wall and floor of the nasal cavity.

#### D. On the face

1. **Palpebral branches** turn upwards and supply the skin of the lower eyelid.
2. **Nasal branches** supply the skin of the side of nose and the mobile part of the nasal septum.
3. **Superior labial branches** supply the skin and mucous membrane of the upper lip.

#### N.B.

The **superior dental plexus** is formed by *posterior, middle, and anterior-superior alveolar nerves*. It is situated in the alveolar process of the maxilla above the sockets of the teeth.

The branches of maxillary nerve are summarized in [Table 10.5](#).

#### **TABLE 10.5**

#### Summary of branches of maxillary nerve

Region	Branches
In the middle cranial fossa	Meningeal branch
In the pterygopalatine fossa	<ul style="list-style-type: none"><li>• Ganglionic branches</li><li>• Posterior-superior alveolar nerves</li><li>• Zygomatic nerve</li></ul>
In the infraorbital canal	<ul style="list-style-type: none"><li>• Middle-superior alveolar nerve</li><li>• Anterior-superior alveolar nerve</li></ul>

On the face

- Palpebral branch
- Nasal branch
- Labial branch

## Pterygopalatine ganglion

The pterygopalatine ganglion (**ganglion of hay fever**) is the *largest peripheral parasympathetic ganglion*. It serves as a relay station for the secretomotor fibres to the lacrimal gland and mucous glands of the nose, palate, pharynx, and paranasal sinuses. Topographically, it is related to the maxillary nerve, but functionally it is connected to the facial nerve through greater petrosal nerve ([Fig. 10.25](#)).

**FIG. 10.25** ■ Pterygopalatine ganglion, its roots and branches.

## Location

It is located deeply in the upper part of the pterygopalatine fossa, suspended from maxillary nerve by two short roots.

## Size

Head of a small pin (4-5 mm in diameter).

## Relations

*Behind:* Pterygoid canal

*Medial:* Sphenopalatine foramen

*In front:* Inferior orbital fissure

*Above:* Maxillary nerve.

## Roots

The roots of pterygopalatine ganglion are as follows:

1. **Motor or parasympathetic root:** It is derived from the nerve of pterygoid canal. It carries preganglionic parasympathetic fibres from superior salivatory nucleus (located in the lower part of the pons). These fibres relay in the ganglion. The postganglionic fibres arise from the cells in the ganglion and supply secretomotor fibres to the lacrimal gland, glands of the nose, palate, nasopharynx, and paranasal sinuses.
2. **Sympathetic root:** It is derived from sympathetic plexus around internal carotid artery via nerve of pterygoid canal. It contains postganglionic fibres from superior cervical sympathetic ganglion. These fibres pass through the ganglion without relay and provide vasomotor supply to the mucous membrane of the nose, palate, pharynx, and paranasal air sinuses.
3. **Sensory root:** It is derived from maxillary nerve and passes through the ganglion without interruption to be distributed through the branches of the ganglion.

## Branches of distribution

The branches of ganglion are actually the branches of maxillary nerve, which passes through the ganglion without relaying. While passing through the ganglion, they incorporate the parasympathetic and sympathetic fibres of the ganglion.

The ganglion provides the following four sets of branches:

1. Orbital
2. Palatine
3. Nasal
4. Pharyngeal.

The **orbital branches** (two or three in number) enter the orbit through inferior orbital fissure and supply orbital periosteum, ethmoidal air sinuses, and secretomotor fibres to the lacrimal gland.

The **palatine branches** include *greater* and *lesser palatine nerves*. The **greater palatine nerve** passes through greater palatine canal and foramen to supply posteroinferior quadrant of the lateral wall of the nose. The **lesser palatine nerves** pass through lesser palatine canals and foramina to supply secretomotor fibres to mucous membrane and glands on the inferior surface of soft palate and hard palate.

The **nasal branches** pass through sphenopalatine foramen to enter the nasal cavity. These are called *posterior-superior nasal nerves*. These are divided into two sets: lateral and medial. The nerves of lateral set supply lateral wall of the nasal cavity, whereas those of medial set supply roof and nasal septum.

The longest branch of medial set is called *nasopalatine/sphenopalatine nerve*. It runs anteroinferiorly in a groove on the nasal septum and leaves the nasal cavity through the incisive foramen to enter the oral cavity where it supplies the anterior part of hard palate.

The **pharyngeal branch** passes through palatovaginal canal and supply the nasopharynx.

### CLINICAL CORRELATION

The allergic conditions, namely, hay fever or cold, cause irritation of nerve of pterygoid canal/pterygopalatine ganglion, which causes congestion of glands of the nose, palate and lacrimal gland. Consequently, the individual suffers from running nose and eyes; for this reason, the nerve of pterygoid canal is called *nerve of hay fever* and the pterygopalatine ganglion is termed *ganglion of hay fever*.

### Third part of the maxillary artery

The third part of the maxillary artery enters the pterygopalatine fossa by passing first between the upper and lower heads of lateral pterygoid and then through the pterygomaxillary fissure. Within the fossa, it lies in front of the pterygopalatine ganglion and divides into its terminal branches. The branches of the third part of the maxillary artery and its distribution are described in detail on pages 134–137 of this chapter.

### Golden Facts to Remember

• <b>Key muscle of the infratemporal fossa</b>	Lateral pterygoid muscle
• <b>All principal muscles of mastication close the mouth except</b>	Lateral pterygoid, which opens the mouth
• <b>Clinically, the most important branch of maxillary artery is</b>	Middle meningeal artery
• <b>Peripheral heart in the region of head and neck</b>	Lateral pterygoid muscle
• <b>Chief elevator of the lower jaw</b>	Masseter
• <b>Largest and only mixed division of trigeminal nerve</b>	Mandibular nerve
• <b>All the branches of anterior division of mandibular nerve are motor except</b>	Buccal nerve, which is sensory and supplies mucous membrane and skin of the cheek
• <b>All the branches of posterior division of mandibular nerve are sensory except</b>	Mylohyoid nerve, which is motor and supplies mylohyoid muscle and anterior belly of digastric muscle
• <b>Most common nerve block given in dentistry</b>	Inferior alveolar nerve block
• <b>Most common dislocation of temporomandibular joint</b>	Anterior dislocation
• <b>Ganglion of hay fever</b>	Pterygopalatine ganglion
• <b>Most common cause of dislocation of temporomandibular joint</b>	Blow to the chin when mouth is widely open (as in laughing or yawning)
• <b>Only parasympathetic ganglion which has four roots</b>	Otic ganglion

## CLINICAL CASE STUDY

A medical student was yawning in the anatomy lecture. Another student sitting by his side hit him on the chin when he yawned widely again. Following a blow on chin, the student got up immediately and wanted to say sorry, but he could not say so because he failed to close his jaws. He kept standing with mouth open widely as his jaw got stuck. The students called

the lecturer for help. The lecturer immediately realized that student's temporomandibular joints are dislocated. He took him to the orofacial surgeon who reduced the **dislocation of TMJ** and the student was relieved of his agony.

## Questions

1. Mention the type of temporomandibular joint and name the bones taking part in its formation.
2. What are the unique features of TMJ?
3. Name the parts of intra-articular disc.
4. Name the commonest variety of TMJ dislocation and how is it reduced.

## Answers

1. It is a condylar type of synovial joint. The bones taking part are head (condyle) of the mandible and mandibular fossa and articular eminence of squamous part of the temporal bone.
2. The unique features of TMJ are as follows:
  - (a) Articular surfaces are covered by plates of articular fibrocartilages.
  - (b) Joint cavity is divided into two compartments by an intra-articular disc.
  - (c) Joints of two sides function together concomitantly to accomplish the movements of the lower jaw.
3. From anterior to posterior, the parts of the intra-articular disc are: (1) anterior extension, (2) anterior thick band, (3) thin intermediate zone, (4) posterior thick band, and (5) bilaminar posterior extension.
4. Anterior dislocation. It is reduced as follows: The mandible is depressed posteriorly by exerting pressure on last molar teeth with thumbs and simultaneously the assistant elevates the chin (also refer to page 146).

---

# Chapter 11: Thyroid and parathyroid glands, trachea and oesophagus

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe thyroid gland under the following headings: (a) location, (b) parts and external features, (c) relations, (d) blood supply, and (e) applied anatomy. **AN 35.2**
- Draw labelled diagrams to show: (a) relations of thyroid gland as seen in transverse section of neck at the level of thyroid isthmus, (b) medial relations of thyroid lobe, (c) arteries supplying thyroid gland, and (d) veins draining thyroid gland.
- Describe the anatomically relevant clinical features of thyroid swellings. **AN 35.8**
- Describe the microanatomical features of thyroid and parathyroid glands. **AN 43.2**
- Give the anatomical basis of: (a) thyroid gland moves up and down during swallowing; (b) during thyroidectomy, superior thyroid artery is ligated nearer to the upper pole of the thyroid lobe while inferior thyroid artery is ligated away from the lower pole, why? (c) thyroid gland is removed with its true capsule, why? (d) thyroid goitre; (e) massive enlargement of thyroid gland leads to dyspnoea, dysphagia and dysphonia; (f) tracheostomy.

The thyroid and parathyroid glands and cervical parts of the trachea and oesophagus are closely related structures.

In the region of neck, thyroid and trachea are routinely examined by

clinicians to diagnose their disorders, for example goitre and tracheal tug. Surgical procedures are commonly performed on these structures, for example thyroidectomy and tracheostomy. Therefore, detailed knowledge of anatomy and relations of these structures is extremely important.

## Thyroid gland (Greek, **thyreos = shield; eidos = form**) AN 35.2

The thyroid gland is so called because it resembles the shields commonly used in ancient Greek. The Greek shield had a notch cut into it for the chin. It is the largest and most superficial endocrine gland of the body. The hormones secreted by the thyroid gland are called thyroid hormones. They include: **triiodothyronine (T<sub>3</sub>)**, **tetraiodothyronine (T<sub>4</sub>)**; and **calcitonin**, which subserve the following functions:

1. Regulate the basal metabolic rate
2. Stimulate the psychosomatic growth of the body
3. Play an important role in calcium metabolism.

### N.B.

The hormone tetraiodothyronine (T<sub>4</sub>) is called as thyroxine.

The thyroid gland was originally known as the **laryngeal gland** and was renamed as 'thyroid gland' by Thomas Wharton in 1646.

### Special features

The special features of the thyroid gland are as follows:

1. It is the only endocrine gland, which is located superficially in the body, hence accessible for physical examination.
2. It is the only endocrine gland that depends on external environment for raw material, i.e. iodine, to synthesize its hormones.
3. It is the only endocrine gland, which does not pour its hormones into blood immediately after their formation but first stores them within the follicles and then releases them in blood for use as and when required.
4. It is one of the organs of the body having a very rich blood flow.

### Location

The thyroid gland is a large butterfly-shaped gland located anteriorly in the lower part of the neck opposite to the C5, C6, C7, and T1 vertebrae (Figs 11.1 and 11.2 ). It lies behind the sternohyoid and sternothyroid muscles, wrapping around the cricoid cartilage and superior tracheal rings.

**FIG. 11.1** ■ Location of the thyroid gland.

**FIG. 11.2 ■** Parts and extent of the thyroid gland.

### Parts and features

- It is H-shaped and brownish red in colour. It consists of vertical right and left lateral lobes and a horizontal isthmus connecting them across the midline. Sometimes, a small **pyramidal lobe** projects upwards from the isthmus usually to the left of the midline. Not infrequently, it is connected to the body of the hyoid bone by a fibrous or fibromuscular band called **levator glandulae thyroideae**.
- Each lateral lobe of the gland extends upwards up to the oblique line of the thyroid cartilage and below up to the 5th or 6th tracheal ring.
- The isthmus extends across the midline in front of the 2nd, 3rd, and 4th tracheal rings.

### Weight and dimensions

The thyroid gland weighs approximately 15–25 g. Each lobe of the thyroid gland is 5 cm long, 3 cm wide, and 2 cm thick ( $5 \times 3 \times 2$  cm). The isthmus measures approximately 1.25 cm in both vertical and transverse diameters.

### **N. B.**

The thyroid gland is usually larger in females and further increases in size during menstruation and pregnancy.

### **Capsule of the thyroid gland (Fig. 11.3 )**

The thyroid gland is invested by two capsules: an inner true capsule and an outer false capsule.

1. **True capsule** : It is formed by the peripheral condensation of the fibrous stroma of the gland.
2. **False capsule** : It is derived from the splitting of the pretracheal fascia. The important features of the false capsule are:
  - (a) It is thin along the posterior border of the lateral lobe.
  - (b) It is thick on the medial surface of the lateral lobe.
  - (c) Traced above, the pretracheal fascia after enclosing the thyroid gland is attached to the oblique lines of the thyroid cartilage, and the body of the hyoid bone in the midline. On the medial surface of thyroid lobe, it thickens to form the **suspensory ligament of Berry** , which connects the lobe to the cricoid cartilage.

**FIG. 11.3** ■ Capsules of the thyroid gland.

The dense venous plexus unlike that of the prostate gland lies deep to true capsule (Fig. 11.3). Therefore, to avoid haemorrhage during thyroidectomy, the thyroid gland is removed along with the true capsule.

### **N.B.**

In case of prostate gland, the venous plexus lies between its true and false capsules and, therefore, during surgical removal of prostate gland (prostatectomy), prostate gland is removed, leaving behind both the capsules.

### **CLINICAL CORRELATION**

- Sometimes, the thyroid tumour extends backwards, as the capsule is thin along the posterior borders of the lateral lobes, compressing the adjacent structures without forming a visible swelling on the front of the neck.
- The **thyroid gland moves up and down during swallowing** because its capsule is attached to laryngeal cartilages and hyoid bone, which moves up and down during swallowing (see Fig 4.12). Thus, thyroid swellings can be distinguished clinically from other swellings in the

region of the neck.

## Relations

### Relations of the thyroid lobe (Figs 11.4 –11.6 )

Each lobe of the thyroid gland is roughly pyramidal (conical) and presents **apex** , **base** , **three surfaces** (lateral, medial, and posterolateral), and **two borders** (anterior and posterior):

- **Apex:** The apex is directed upwards and slightly laterally. It extends up to the oblique line of thyroid cartilage where it is limited above by the attachment of sternothyroid muscle. The apex is sandwiched between the inferior constrictor medially and sternothyroid laterally (Fig. 11.4 ).
- **Base:** The base extends up to the 5th or 6th tracheal ring. It is related to inferior thyroid artery and recurrent laryngeal nerve.
- **Lateral (superficial) surfaces:** It is convex and is covered by (Fig. 11.5 ):
  - (a) Three strap muscles (sternothyroid, sternohyoid, and superior belly of omohyoid)
  - (b) Anterior border of sternocleidomastoid overlapping it inferiorly.
- **Medial surface** is related to (Fig. 11.6 ):
  - (a) *Two tubes:* trachea and oesophagus
  - (b) *Two muscles:* inferior constrictor and cricothyroid
  - (c) *Two cartilages:* cricoid and thyroid.
- **Posterolateral surface** is related to (Fig. 11.5 ) carotid sheath and its contents (common carotid artery, internal jugular vein, and vagus nerve). The ansa cervicalis is embedded in the anterior wall of the sheath, whereas cervical sympathetic chain lies posterior to sheath in front of prevertebral fascia.
- **Anterior border** is thin and separates superficial and medial surfaces. It is related to anterior branch of the superior thyroid artery.
- **Posterior border** is thick and rounded. It separates the medial and the posterior surfaces. It is related to:
  - (a) Longitudinal arterial anastomosis between superior and inferior thyroid arteries
  - (b) Parathyroid glands.

**FIG. 11.4 ■** Relations of the lateral lobe of the thyroid gland: ( **A** ) upward extension of the thyroid lobe and muscles attached to the oblique line of the thyroid cartilage; ( **B** ) the apex is sandwiched between the inferior constrictor and sternothyroid.

**FIG. 11.5 ■** Transverse section of the anterior part of the neck at the level of thyroid isthmus showing relations of the thyroid gland.

**FIG. 11.6 ■** Medial relations of the lateral lobe of the thyroid gland. The figure also shows intimate relationship of the external and recurrent laryngeal nerves with the superior and inferior thyroid arteries, respectively.

### Relations of isthmus

The isthmus is horizontal and presents **two surfaces** : anterior and posterior and **two borders** : superior and inferior.

- *Anterior surface* is related to:
  - (a) Strap muscles (sternohyoid and sternothyroid)
  - (b) Anterior jugular veins
- *Posterior surface* is related to 2nd, 3rd, and 4th tracheal rings.
- *Superior border* is related to anastomosis between the anterior branches of two superior thyroid arteries.
- *Inferior border* . Along this border, inferior thyroid vein emerges and

thyroidea ima artery (when present) enters.

## Arterial supply

The gland is highly vascular and is supplied by the following **arteries** (Fig. 11.7 ):

1. **Superior thyroid artery** : It is a branch of the external carotid artery. It runs downwards and forwards in company with the external laryngeal nerve, which it leaves near the upper pole of the thyroid lobe. At the apex of the lobe, it divides into anterior and posterior branches. The anterior branch first descends along the anterior border of the lobe, and then continues along the upper border of the isthmus to anastomose with its fellows of opposite side. The posterior branch descends along the posterior border of the lobe to anastomose with the ascending branch of the inferior thyroid artery.
  - Superior thyroid artery supplies the upper one-third of the lobe and upper half of the isthmus.
2. **Inferior thyroid artery** : It is a branch of thyrocervical trunk from the first part of the subclavian artery. It first runs upwards along the medial border of scalenus anterior, and then passes medially behind the carotid sheath to reach the back of the thyroid lobe, where it is intimately related to the recurrent laryngeal nerve. The *recurrent laryngeal nerve presents a variable relationship with the artery* . It may pass behind or in front of the loop of the artery or between the branches of the artery (Fig. 11.8 ). The artery gives four or five branches. One ascending branch anastomoses with the posterior branch of the superior thyroid artery.
  - The inferior thyroid artery supplies lower two-third of the lobe and lower half of the isthmus.
3. **Thyroidea ima artery (in 7.5% cases)** : It is a branch of the brachiocephalic trunk or may arise directly from the arch of aorta. It enters the isthmus from below.
4. **Accessory thyroid arteries**: They arise from tracheal and oesophageal arteries.

**FIG. 11.7 ■** Arterial supply of the thyroid gland.

**FIG. 11.8 ■** Variable relationship of recurrent laryngeal nerve with the inferior thyroid artery.

## Venous drainage

The venous blood from the thyroid gland is drained by three set of veins (Fig. 11.9 ), namely:

1. **Superior thyroid vein** : It emerges at the upper pole of the thyroid lobe, runs upwards and laterally, and drains into the internal jugular vein.
2. **Middle thyroid vein** : This short, wide venous channel emerges at the middle of the lobe to soon enter the internal jugular vein.
3. **Inferior thyroid vein/veins** : They emerge at the lower border of the isthmus, form plexus in front of the trachea and then run downwards to drain into the left brachiocephalic vein.
4. Sometimes a fourth **thyroid vein (of Kocher)** emerges between the middle and inferior thyroid veins to drain into the internal jugular vein.

**FIG. 11.9** ■ Venous drainage of the thyroid gland.

**Lymphatic drainage (Fig. 11.10 )**

The lymph vessels draining the thyroid gland are arranged into two groups, upper and lower, and they follow the arteries:

1. The **upper group** drains into the prelaryngeal (lying in front of the larynx) and upper deep cervical (jugulodigastric) lymph nodes.
2. The **lower group** drains into pretracheal and lower deep cervical lymph nodes and group of lymph nodes along the recurrent laryngeal nerves. Those from lower part of isthmus drain into retrosternal or brachiocephalic nodes lying in the superior mediastinum.

**FIG. 11.10 ■** Lymphatic drainage of the thyroid gland.

The upper lymphatics follow superior thyroid artery and lower lymphatics follow the inferior thyroid arteries.

### **Nerve supply**

The thyroid gland is supplied by both sympathetic and parasympathetic nerve fibres:

1. The **parasympathetic supply** is derived from the vagus and recurrent laryngeal nerves.
2. The **sympathetic supply** is derived from the superior, middle, and inferior cervical sympathetic ganglia, but mainly from the middle one.

### **Microanatomical features (Fig. 11.11 ) AN 43.2**

The thyroid gland consists of thyroid follicles and interspersed connective tissue. It consists of two types of secretory cells: follicular and parafollicular.

**FIG. 11.11 ■** Microscopic structure of the thyroid gland.

The **follicular cells** are cuboidal epithelial cells forming the wall of spherical thyroid follicles. They secrete two hormones: thyroxine and triiodothyronine.

These hormones are essential for normal growth and development, especially of the skeletal and nervous system.

The **parafollicular cells or C-cells** lie mainly between the basement membrane and the follicular cells. Some of them also lie in the spaces

between the follicles. They secrete a hormone called **thyrocalcitonin** (also called **calcitonin** ). It plays an important role in calcium metabolism. It reduces the blood calcium level by reducing the reabsorption of the calcium by the renal tubules. Its effects are opposite to that of parathormone.

## CLINICAL CORRELATION AN 35.8

**Hypothyroidism** It occurs when there is insufficient secretion of the T<sub>3</sub> and T<sub>4</sub>. The decreased levels of T<sub>3</sub> and T<sub>4</sub> causes increased secretion of TSH.

It may be congenital or acquired.

The *congenital hypothyroidism* (or *hypothyroidism in infants* ) occurs due to poorly developed thyroid glands, lack of iodine in gravid mother's diet.

The *acquired hypothyroidism* (*hypothyroidism in adults* ) usually occurs due to autoimmune disorders called **Hashimoto's disease** or iodine deficiency in diet.

Congenital hypothyroidism causes *cretinism* in children while hypothyroidism in adults causes myxoedema (for details, see [Chapter 13](#) , Endocrine System in book *General Anatomy with Systemic Anatomy, Radiological Anatomy, Medical Genetics*, 4th edn by Vishram Singh).

**Hyperthyroidism (or thyrotoxicosis)** It occurs because of excess secretion of T<sub>3</sub> and T<sub>4</sub>. The most common cause of hypothyroidism is Graves' disease. The thyrotoxicosis clinically presents as tachycardia, tremors, and systolic bruit. The main effects are because of increased BMR.

- **Goitre:** Any enlargement of the thyroid gland *except* that during menstruation and lactation is called *goitre* . It may be associated with hypofunction or hyperfunction of the gland.
- **Simple goitre/puberty goitre:** It is an enlargement of the thyroid gland without signs of hyperthyroidism. It occurs because of deficiency of iodine in diet. Remember iodine is essential for synthesis of thyroid hormone. The decreased levels of T<sub>3</sub> and T<sub>4</sub> lead to increased secretion of TSH from the pituitary gland. The TSH causes hyperplasia of the thyroid gland. Simple goitre commonly occurs in females at the age of puberty; hence, it is also called *puberty goitre*.

*Effects of massive enlargement of thyroid gland (goitre; [Fig. 11.12](#) ):* The

thyroid gland can enlarge backwards or downwards but it cannot enlarge upwards because of attachment of its fascial sheath and sternothyroid muscle to the thyroid cartilage.

◊The backward enlargement is common because the thyroid capsule is relatively thin posteriorly. In backward enlargement, the gland buries itself around the sides of trachea and oesophagus.

◊This results in three characteristic pressure symptoms, namely:

- **Dyspnoea** (difficulty in breathing), due to pressure on trachea.
- **Dysphagia** (difficulty in swallowing), due to pressure on oesophagus.
- **Dysphonia** (hoarseness of voice), due to pressure on the recurrent laryngeal nerve, which lies in the tracheoesophageal groove.

♣*Mnemonic = 3D*

- **Retrosternal goitre:** The downward expansion behind the sternum is called retrosternal goitre. It can compress trachea leading to dangerous dyspnoea.
  - ◊It can also cause severe venous compression leading to venous congestion.
- **Thyroidectomy:** It is removal of complete thyroid gland with its true capsule.
- **Subtotal thyroidectomy:** In this, posterior parts of both thyroid lobes are left behind. This is done to avoid the risk of inadvertent removal of parathyroid glands leading to hypoparathyroidism and to avoid postoperative myxoedema due to deficiency of thyroid hormones.
- **Ligation of thyroid arteries during thyroidectomy:** The superior thyroid artery and the external laryngeal nerve diverge from each other near the apex, the artery lies superficial and the nerve lies deep to the apex. Therefore, during thyroidectomy, superior thyroid artery should be ligated as close to the apex of thyroid lobe as possible to avoid injury to the external laryngeal nerve.
  - ◊The recurrent laryngeal nerve lies very close to the inferior thyroid artery near the base of the thyroid lobe. Therefore, during thyroidectomy, the inferior thyroid artery should be ligated as away from the base of the thyroid lobe as possible to avoid injury to the recurrent laryngeal nerve.
- **Benign tumours** may compress or also displace the neighbouring

structures, whereas *malignant growth* tends to invade surrounding structures.

**FIG. 11.12** ■ Massive enlargement of the thyroid gland.  
(Source: page 267, *Short Cases in Clinical Medicine* , 5e,  
ABM Abdullah, Copyright Elsevier 2013, All rights  
reserved.)

### **Development (Fig. 11.13 )**

Initially, thyroid gland forms in the floor of primitive pharynx, then descends down the neck to lie in the adult anatomical position. The details are as follows:

**FIG. 11.13 ■** Development of the thyroid gland: ( **A** ) different stages in the development; ( **B** ) shows the path taken by thyroglossal duct as it migrates inferiorly.

The thyroid gland begins to develop as endodermal thickening in the midline of the floor of the primitive pharynx immediately behind the tuberculum impar during 3rd week of intrauterine life. This thickening is soon depressed below the surface to form a diverticulum called **thyroglossal duct**. This duct grows downwards across the tongue and then descends in front of the neck. In the neck, it passes in front of hyoid bone, winds around its lower border to become retrohyoid, and finally descends below the hyoid with slight inclination to one side, usually to left to reach its definitive position (by the end of the 7th week) where its tip bifurcates and proliferates to form the bilateral terminal swellings, which expand to form the thyroid gland. A portion of the duct near its tip sometimes forms the **pyramidal lobe**. The remaining duct disappears. The site of origin of thyroglossal duct is, however, marked by **foramen caecum** at the junction of the anterior two-third and posterior one-third of the tongue in adults (Fig. 11.13). The thyroid is the earliest glandular tissue to develop and becomes functional during the third month.

### **N.B.**

The ultimobranchial bodies from 5th pharyngeal pouches and neural crest cells become incorporated secondarily into thyroid gland and form parafollicular cells or C-cells.

## CLINICAL CORRELATION

**Congenital anomalies:** The development of the thyroid gland may account for the following common congenital anomalies:

- ⊖ *Thyroglossal cyst/fistula:* Thyroglossal duct may persist and lead to formation of *thyroglossal cyst* and *fistula*.
- ⊖ *Ectopic thyroid:* The thyroid gland (thyroid tissue) may be found at an abnormal position anywhere along the course of thyroglossal duct.
  - (a) At the base of the tongue (*lingual thyroid*). In lingual thyroid, the mass of thyroid tissue is located within the tongue just beneath the foramen caecum, and if large, it may cause difficulty in swallowing by the infant.
  - (b) Above, behind, or below the hyoid bone (*suprahyoid*, *retrohyoid*, or *infrahyoid thyroid*).
- ⊖ One of the lobes may be absent.
- ⊖ Isthmus may be absent.
- ⊖ Descent of the thyroglossal duct may go beyond the definitive position in the neck to superior mediastinum (*retrosternal thyroid*).
- ⊖ Thyroid tissue may be situated away from the normal course of the thyroglossal duct, namely, in relation to carotid sheath, in the mediastinum, in the pericardium (*aberrant thyroid*).

## Parathyroid glands

These are two pairs of small endocrine glands behind thyroid. Two parathyroid glands, one superior and one inferior are located along the posterior borders of each thyroid lobe within each thyroid capsule ([Fig. 11.14](#)). They appear as small yellowish-brown bodies.

**FIG. 11.14 ■** Location of the parathyroid glands: ( **A** ) posterior aspect of the thyroid gland; ( **B** ) section through thyroid lobe along with its capsule.

The parathyroid glands secrete *parathormone* (a hormone), which maintains blood calcium level by mobilizing the calcium from the bones. Its action is opposite to that of *calcitonin* secreted by the thyroid.

### Location

The **superior parathyroid** lies at the middle of the posterior border of the thyroid lobe above the level at which inferior thyroid artery crosses the recurrent laryngeal nerve. They develop from 4th pharyngeal pouch and hence also termed as *parathyroid-IV*.

The **inferior parathyroid** lies on the posterior border of the thyroid lobe near its lower pole, below the inferior thyroid artery. They develop from 3rd pharyngeal pouch, hence also termed as *parathyroid-III*.

## N.B.

- The **superior parathyroid** is fairly constant in position and usually lies at the middle of the posterior border of the thyroid gland.
- The **inferior parathyroid** is more variable in position. It may lie: (1) within the thyroid capsule, below the loop of the inferior thyroid artery; (2) outside the capsule, above the loop of the thyroid artery; or (3) within the substance of the thyroid gland.

## Size and shape

They are small, oval, or lentiform in shape. Each gland measures approximately 6 mm in length, 4 mm in breadth, and 2 mm in thickness, the size of a split pea and weighs approximately 50 mg.

## Blood supply

The parathyroid glands have rich blood supply.

The **superior parathyroid** is supplied by the superior parathyroid artery, a branch from anastomotic artery joining the superior and the inferior thyroid arteries, or from inferior thyroid artery.

The **inferior parathyroid** is supplied by the inferior parathyroid artery, a branch of inferior thyroid artery. The inferior parathyroid artery is a good guide to locate the parathyroid gland, especially if it lies below the thyroid gland.

## Nerve supply

The parathyroid glands are supplied by the sympathetic fibres, derived from the superior and middle cervical sympathetic ganglia or sympathetic plexus around the inferior thyroid artery. These fibres are vasomotor in nature.

The secretory activity of the gland is controlled by blood calcium level; low level of calcium stimulates secretion, whereas high levels of calcium inhibit the secretion.

## Microanatomical features and functions

The parenchymal cells of the parathyroid gland form irregular anastomosing cords or groups of cells. The parenchymal cells are of two types: **principal or chief cells** and **oxyphil cells**. The chief cells form the major population and secrete parathyroid hormone known as **parathormone**. The oxyphil cells form minor population and their function is not known.

The parathyroid hormone plays an important role in calcium metabolism. It maintains the blood calcium level by:

1. Enhancing the mobilization of calcium from bones by osteoclastic activity.
2. Increasing the reabsorption of calcium by proximal renal tubules.
3. Promoting the absorption of dietary calcium from small intestine.

## CLINICAL CORRELATION

- **Hypoparathyroidism** may occur spontaneously or because of inadvertent removal of parathyroid glands during thyroidectomy. It results in *tetany* because of low blood calcium level. Clinically, the tetany presents as increased neuromuscular excitability, causing convulsions and carpopedal spasms (Fig. 11.15 ).
- **Hyperparathyroidism** is seen in the tumours of the parathyroid glands. The increased amount of parathormone: (1) removes excessive calcium from bones, which makes the bones soft because of decalcification leading to a clinical condition called *generalized osteitis fibrosa* , and (2) may cause *formation of stones in the kidney* .

**FIG. 11.15** ■ Hand spasm in tetany.

## Development (Fig. 11.16 )

The **inferior parathyroid gland** develops from the 3rd pharyngeal pouch along with thymus. As the thymic diverticulum migrates inferiorly in the neck, it pulls inferior parathyroid with it. Consequently, the inferior parathyroid comes to lie finally on the posterior surface of the thyroid lobe near the lower pole.

The **superior parathyroid gland** develops from the 4th pharyngeal pouch and finally lies on the posterior surface of the thyroid lobe at the level of the isthmus.

**FIG. 11.16** ■ Development of the parathyroid gland: sites of development and final positions taken by them.  
III= Third pharyngeal pouch, IV= fourth pharyngeal pouch.

## Trachea

The trachea is a noncollapsible membranocartilaginous tube forming the beginning of lower respiratory passage.

### Extent

Trachea is a midline structure which passes inferiorly and slight posteriorly. It extends from the lower border of cricoid cartilage at the lower border of the C4 vertebra in cadaver and to the lower border of T6 vertebra in living person, where it terminates by dividing into right and left principal bronchi, slightly to the right of median plane.

### Dimensions

The trachea is about 4–5 inches (10–12 cm) long tube. The upper half of

trachea is located in the neck (**cervical part**) , whereas the lower half lies in the superior mediastinum of the thoracic cavity (**thoracic part**) .

The external diameter of trachea is 2 cm in males and 1.5 cm in females.

The lumen is smaller in living human than that in cadavers. It is approximately 3 mm in newborns and remains so up to the 3rd year of life; thereafter, lumen increases by 1 mm each year up to 12 years, after which it remains fairly constant.

This knowledge is very important for the anaesthetists to select appropriate size of tracheal tube to be inserted into the trachea in children during general anaesthesia.

## **Structure**

The trachea is composed of approximately 16–20 C-shaped rings of hyaline cartilage lying one above the other. The cartilages are deficient posteriorly where the gap is filled by connective tissue and involuntary muscle called **trachealis** . The absence of cartilages on the posterior aspect allows expansion of oesophagus during deglutition. In cross-section, the trachea appears D-shaped or horseshoe-shaped. The following text deals with cervical part in detail; however for thoracic part, refer *Textbook of Anatomy: Upper Limb and Thorax*, Vol. I, 4ed. by Vishram Singh.

## **Cervical part of trachea**

The cervical part of the trachea is approximately 7 cm in length and extends from the lower border of cricoid cartilage to the upper border of manubrium sterni. It extends downwards and slightly backwards in front of the oesophagus following curvature of the cervical spine and enters the thoracic cavity in the median plane with slight deviation on the right side.

## **Relations of the cervical part of trachea**

In the neck, the trachea is relatively superficial and has the following relations:

*Anteriorly* , from superficial to deep it is related to:

- (a) Skin
- (b) Superficial fascia containing anterior jugular veins and jugular venous arch (crossing in the suprasternal space of Burns)
- (c) Investing layer of deep cervical fascia
- (d) Sternothyroid and sternohyoid muscles

- (e) Isthmus of thyroid gland in front of the 2nd, 3rd, and 4th tracheal rings
- (f) Inferior thyroid veins and arteria thyroidea ima (occasional)
- (g) Left brachiocephalic vein in children may rise in the neck
- (h) Thymus gland (in children)
- (i) Brachiocephalic artery (sometimes) in children

*Posteriorly*, it is related to:

- (a) Oesophagus
- (b) Recurrent laryngeal nerve in the tracheoesophageal groove (on each side)

*On each side*, it is related to:

- (a) Lobe of thyroid gland extending up to the 5th or 6th tracheal ring
- (b) Common carotid artery in the carotid sheath.

### Blood supply and lymphatic drainage

The **arterial supply** of the cervical part of trachea is derived mainly from branches of the inferior thyroid arteries.

The **veins from trachea** drain into the left brachiocephalic vein.

The lymph from trachea drains into pre- and paratracheal nodes.

### Nerve supply

This is by sympathetic and parasympathetic fibres.

The **parasympathetic fibres** are derived from vagus through the recurrent laryngeal nerve. They are secretomotor and sensory to the mucous membrane and motor to the trachealis muscle.

The **sympathetic fibres** are derived from the middle cervical sympathetic ganglion. They are vasomotor in nature.

### CLINICAL CORRELATION

**Tracheostomy ( Fig 11.17 ):** It is a life-saving surgical airway management procedure, done in cases of laryngeal obstruction. The tracheostomy is commonly done in the retrothyroid region after displacing the isthmus of the thyroid gland upwards or downwards.

After displacing the isthmus, the trachea is opened by a vertical incision in the region of the 3rd and 4th or 2nd and 3rd tracheal rings. This is then converted into circular opening and tracheostomy tube is inserted.

If the tracheostomy is performed above the isthmus, it is called *high*

*tracheostomy*, and if it is performed below the isthmus, it is called *low tracheostomy*.

The low tracheostomy is risky in children owing to shortness of the neck and presence of thymus and left brachiocephalic vein and sometimes brachiocephalic artery. These structures, if injured, will cause alarming haemorrhage.

**FIG. 11.17 ■ Tracheostomy.**

## Oesophagus

The oesophagus is 25-cm-long muscular tube, which connects pharynx with the stomach. The oesophagus is kept collapsed anteroposteriorly between trachea and vertebral column. Its expansion occurs only when bolus of food passes through it.

The oesophagus begins as a continuation of pharynx at the lower border of

cricoid cartilage opposite the lower border of C6 vertebra.

It passes downwards in front of the vertebral column behind trachea, traverses superior and posterior mediastina of thorax, passes through the oesophageal opening of the diaphragm and ends at the cardiac orifice of the stomach in the abdomen approximately 2.5 cm to the left of the median plane.

The oesophagus is divided into three parts: **cervical, thoracic** , and **abdominal** .

### **N. B.**

The pharyngoesophageal junction is the narrowest part of the digestive tube *except* that of the vermiform appendix.

Only cervical part of oesophagus is discussed here. The thoracic and abdominal parts are described in Vol I and Vol II of this book respectively.

### **Cervical part of the oesophagus**

It extends from the lower border of cricoid cartilage to the superior border of manubrium sterni. It begins in the midline but inclines slightly to the left as it descends.

### **Relations of cervical part of the oesophagus**

*Anteriorly*, it is related to:

- (a) Trachea
- (b) Recurrent laryngeal nerve

*Posteriorly*, it is related to:

- (a) Prevertebral fascia
- (b) Longus colli muscles
- (c) Vertebral column.

*On each side* , it is related to:

- (a) Lobe of the thyroid gland
- (b) Common carotid artery
- (c) Thoracic duct on the left side.

### **N. B.**

The prevertebral layer of deep cervical fascia forms a movable base on which the trachea and oesophagus move up and down during swallowing and phonation.

## Blood supply and lymphatic drainage

The cervical part of the oesophagus is supplied by the **inferior thyroid arteries**.

The **veins** from this part drain into inferior thyroid veins and left brachiocephalic vein.

The lymph vessels from the cervical part of oesophagus drain into pretracheal and deep cervical lymph nodes.

### CLINICAL CORRELATION

- The left margin of the oesophagus projects laterally from behind trachea in region of the neck. Therefore, cervical part of oesophagus can be mobilized and exposed surgically more easily from the left side.
- The interior of the oesophagus can be examined in vivo by oesophagoscope. This procedure helps to obtain tissue biopsy or removal of swallowed foreign body.

### Golden Facts to Remember

• <b>Largest endocrine gland of the body</b>	Thyroid gland
• <b>Earliest glandular tissue to develop and become functional</b>	Thyroid tissue
• <b>Most vascular endocrine gland in the body</b>	Thyroid gland (adrenal medulla is also equally vascular)
• <b>Most common form of incomplete descent of thyroid</b>	Lingual thyroid
• <b>Most common site of thyroglossal cyst</b>	Subhyoid
• <b>Most common cause of hypercalcaemia in adult</b>	Primary hyperparathyroidism
• <b>Most common mode of clinical presentation of hyperparathyroidism</b>	Renal stones
• <b>Most common cause of hypoparathyroidism</b>	Inadvertent removal during surgery, for example, thyroidectomy

• <b>Most preferred site of the tracheostomy</b>	2nd or 3rd tracheal rings
• <b>Commonest site of the cancer oesophagus</b>	Middle one-third of oesophagus
• <b>Most common site of the adenocarcinoma of oesophagus</b>	Lower one-third

## CLINICAL CASE STUDY

A 55-year-old woman complained of midline nodular swelling on the front of her neck, which moved up and down during swallowing. On physical examination, it was found that she had slight tremors on outstretched hands, her pulse rate was 110 per minute, BP 150/100 mm Hg and there was slight bulging of her eyes. She also told that she had lost weight and felt feverish. She was diagnosed as a case of ***toxic goitre***.

### Questions

1. What is goitre?
2. Why do thyroid swellings move up and down during swallowing?
3. Mention anatomical basis of high body temperature, weight loss, high blood pressure, and exophthalmos.

### Answers

1. Any enlargement of the thyroid gland except that during menstruation and lactation is called goitre.
2. The thyroid gland is enclosed in pretracheal fascia which anchors the gland with laryngeal cartilages (e.g., thyroid and cricoid). Because larynx moves up and down during swallowing, thyroid swelling also moves with it.
3. Toxic goitre is associated with hypersecretion of the thyroid hormones, which increases the rate of metabolism leading to high body temperature, weight loss, high blood pressure, and exophthalmos.

---

# Chapter 12: Pre- and paravertebral regions and root of the neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Enumerate the scalene muscles under the following headings: (a) origin, (b) insertion, (c) nerve supply, and (e) actions. **AN 29.4**
- Give the anatomical basis of: (a) scalene syndrome and (b) phrenic crush.
- Describe the clinical features occurring due to compression of subclavian artery and lower trunk of brachial plexus by first cervical rib. **AN 35.9**
- Write short notes on: (a) scalenus anterior muscle, (b) scalenovertebral triangle/triangle of vertebral artery, (c) scalene triangle, (d) cervical plexus, and (e) phrenic and accessory phrenic nerves.
- Describe the extent, formation, relation, and branches of cervical sympathetic chain. **AN 35.6**
- Describe the anatomical basis of Horner's syndrome. **AN 31.3**

The prevertebral region of the neck extends from 1st cervical vertebra to the upper two thoracic vertebrae. The upper two thoracic vertebrae are included because they are visible in the background of the root of the neck because of forward slope of the superior thoracic aperture. The paravertebral region lies on either side of prevertebral region and extends from transverse process of first cervical vertebra to the 1st rib. The root of the neck is defined as the area of the neck immediately above the thoracic inlet ([Fig. 12.1](#)). The structures

encountered in these regions include anterior and lateral vertebral muscles, cervical plexus, cervical sympathetic chain, and large vessels.

**FIG. 12.1 ■** Bony features in the pre- and paravertebral regions and the root of the neck.

## **Prevertebral (anterior vertebral) muscles**

The anterior vertebral muscles lie in front of the cervical part of the vertebral column. All of them are covered by prevertebral fascia and supplied by ventral rami of cervical nerves. They form the posterior boundary of the retropharyngeal space. As a group, they flex the neck and the head on the neck.

The anterior vertebral group of muscles include (Figs 12.2 and 12.3 ):

1. Rectus capitis anterior
2. Rectus capitis lateralis
3. Longus cervicis (longus colli)
4. Longus capitis.

**FIG. 12.2 ■** Attachments of the anterior vertebral muscles.

### **Rectus capitis anterior (Fig. 12.2 )**

It arises from the anterior surface of the lateral mass of the atlas, extends upwards and slightly medially to be inserted on the inferior surface of the basiocciput just in front of the occipital condyle.

### **Rectus capitis lateralis (Fig. 12.2 )**

It arises from the upper surface of the transverse process of the atlas, runs upwards and laterally to be inserted on inferior surface of the jugular process of the occipital bone. It is separated from rectus capitis anterior by the *ventral ramus of the 1st cervical nerve*, which supplies both these muscles.

### **Longus cervicis (longus colli, Fig. 12.2 )**

This is the longest and medial of the prevertebral muscles. It extends from anterior tubercle of the atlas to the anterior aspect of the 3rd thoracic vertebra.

The longus colli consists of three parts, namely:

1. Upper oblique part
2. Middle vertical part
3. Lower oblique part.

The **upper oblique part** arises from anterior tubercles of transverse processes of C3, C4, and C5 vertebrae, passes upwards and medially to be inserted on the anterior arch of the atlas to the side of the anterior tubercle.

The **middle vertical part** arises from the front of bodies of the upper three thoracic and lower three cervical vertebrae and ascends up, to be inserted on the front of the bodies of the 2nd, 3rd, and 4th cervical vertebrae.

The **inferior oblique part** is the smallest. It arises from front of the bodies of the upper two or three thoracic vertebrae, runs upwards and laterally to be inserted onto the anterior tubercles of the transverse processes of the 5th and 6th cervical vertebrae.

### **Nerve supply**

The longus colli is supplied segmentally by branches from anterior primary rami of C2–C6 spinal nerves.

### **Actions**

It bends the neck forwards. In addition, upper oblique part may flex the neck laterally and lower oblique part rotates the neck to the opposite side.

### **Longus capitis (Fig. 12.3 )**

It arises from anterior tubercles of the transverse processes of C3, C4, C5, and C6 vertebrae, corresponding to the origin of scalenus anterior muscle and

inserted on the inferior surface of the basilar part of the occipital bone along the side of pharyngeal tubercle. It is narrow below and thick above, and overlaps the longus colli (cervicis) muscle.

**FIG. 12.3 ■** Attachment of the longus capitis muscle.

### **Nerve supply**

It is supplied by branches of anterior primary rami of C1, C2, and C3 spinal nerves.

### **Actions**

Longus capitis flexes the head.

## **Paravertebral (lateral vertebral) muscles**

The paravertebral muscles extend from transverse processes of cervical vertebrae to the upper two ribs. They can, therefore, either elevate these ribs or bend the cervical part of the vertebral column laterally.

These muscles form a thick mass behind the prevertebral fascia and are supplied by twigs from ventral rami of the lower five or six cervical spinal nerves.

The lateral vertebral group of muscles consists of scalene muscles.

The scalene muscles, usually three in number, are as follows:

1. Scalenus posterior
2. Scalenus medius
3. Scalenus anterior.

### **N. B.**

The scalenus medius is the largest and scalenus posterior is the smallest paravertebral muscle.

### **Scalenus posterior (Fig. 12.4 )**

It is the **smallest** and most deeply situated of all scalene muscles.

**FIG. 12.4 ■** Attachments of the scalenus posterior muscle.

### Origin

From posterior tubercles of the transverse processes of C4, C5, and C6 vertebrae.

### Insertion

On to the outer surface of 2nd rib, behind the tubercle for serratus anterior.

### Nerve supply

By ventral rami of the lower three cervical (C6, C7, and C8) spinal nerves.

### Actions

1. When the 2nd rib is fixed, it bends the cervical vertebral column to the same side.
2. When upper attachment is fixed, it helps to elevate the 2nd rib, and thus acts as an accessory muscle of respiration.

### **Scalenus medius (Fig. 12.5 ) AN 29.4**

It is the **longest** and **largest** of all the scalene muscles.

**FIG. 12.5 ■** Attachments of the scalenus medius muscle.

### Origin

From posterior tubercles of the transverse processes of C2–C6 cervical vertebrae.

### Insertion

On to the upper surface of the 1st rib between the tubercle of the rib and groove for subclavian artery.

### Nerve supply

By ventral rami of C3–C8 spinal nerves.

### Actions

1. When 1st rib is fixed, it bends the neck to the same side.
2. When upper end is fixed, it elevates the 1st rib and thus acts as an *accessory muscle of respiration*.

### **Scalenus anterior (Fig. 12.6 ) AN 29.4**

It is the **most superficial** of scalene muscles and lies deep to sternocleidomastoid muscle. It is the **key muscle at the root of neck** because of its intimate relations to many structures in this region. It provides a useful *surgical landmark* .

**FIG. 12.6 ■** Attachments of the scalenus anterior muscle.

### **Origin**

From anterior tubercles of transverse processes of C3, C4, C5, and C6 vertebrae (i.e., all typical vertebrae).

## Insertion

The fibres converge and descend almost vertically to be inserted by a narrow, flat tendon to the scalene tubercle on the inner border of the 1st rib and to the ridge on the upper surface of the rib anterior to the groove for the subclavian artery.

## Nerve supply

By ventral rami of C4, C5, and C6 spinal nerves.

## Actions

1. Acting from below, it bends the neck forwards and laterally and rotates it to the opposite side.
2. Acting from above, it helps to elevate the 1st rib and thus acts as an accessory muscle of respiration.

## Relations of the scalenus anterior muscle (Fig. 12.7 )

The scalenus anterior muscle forms an important landmark at the root of the neck because phrenic nerve passes superficial to it, subclavian artery deep to it and brachial plexus lies at its lateral border.

**FIG. 12.7** ■ Schematic sagittal section to show the

anterior and posterior relations of the scalenus anterior muscle.

Therefore, the relations of scalenus anterior muscle are very important.

*Anterior relations:*

1. **Phrenic nerve** runs downward across the anterior surface of the muscle deep to prevertebral fascia.
2. **Two arteries** – transverse cervical and suprascapular – cross the anterior surface of muscle from medial to lateral side.
3. **Two veins**
  - (a) *Anterior jugular vein* crosses the muscle from above downwards.
  - (b) *Subclavian vein* crosses the anterior surface near insertion from lateral to medial side.
4. **Two muscles**
  - (a) *Inferior belly of omohyoid* crosses the anterior surface from lateral to medial side because it takes origin from scapula run as upwards and medially towards intermediate tendon.
  - (b) *Sternocleidomastoid (clavicular head)* overlaps the muscle.
5. **Carotid sheath** lies vertically in front of the muscle.
6. **Clavicle** crosses from medial to lateral side.

*Posterior relations:*

1. **Roots of brachial plexus** separate the scalenus anterior from scalenus medius.
2. **Subclavian artery** passes deep to scalenus anterior near its insertion from medial to lateral side, separating it from scalenus medius.
3. Scalenus medius muscle (medial part).
4. Cervical pleura.
5. Suprapleural membrane.

*Other relations:*

1. The **medial border** of scalenus anterior forms the lateral boundary of the **scalenovertbral triangle or triangle of the vertebral artery**. The contents of this triangle form the medial relations of the scalenus anterior.
2. The **lateral border** of the scalenus anterior is related to trunks of brachial plexus, which emerge underneath it.

3. The **upper part of scalenus anterior** is separated from longus capitis by the ascending cervical artery.

### **Interscalene/scalene triangle (Fig. 12.8 )**

It is a narrow triangular gap above the 1st rib between scalenus anterior and scalenus medius. The subclavian artery and roots and trunks of brachial plexus pass through this space.

**FIG. 12.8** ■ Scalene triangle.

### **CLINICAL CORRELATION**

**Scalene syndrome: (AN 35.9 )** It consists of group of signs and symptoms produced because of **compression of lower trunk of brachial plexus (C8 and T1) and subclavian artery in the scalene triangle either because of raising of its base by the cervical rib, if present, or**

***because of spasm of scalene muscles.***

*Clinically, this syndrome presents as:*

- (a) Tingling and numbness along the inner border of forearm and hand, that is, along the distribution of C8 and T1 spinal nerves
- (b) Progressive paresis and wasting of intrinsic muscles of the hand (most of them are supplied by C8 and T1 spinal nerves)
- (c) Ischaemic pain and absence of radial pulse due to compression of subclavian artery

### **Scalenovertebral triangle (triangle of vertebral artery; Fig. 12.9 )**

It is a deeply placed triangular space at the root of the neck between scalenus anterior laterally and longus colli (cervicis) medially. The cervical pleura and apex of lung project upward into this space.

#### **Boundaries:**

<i>Medial</i>	Lower oblique part of the longus colli
<i>Lateral</i>	Medial border of scalenus anterior
<i>Apex</i>	Transverse process of C6 vertebra
<i>Base</i>	First part of the subclavian artery
<i>Floor (posterior wall)</i>	From above downwards, it is formed by: <ul style="list-style-type: none"><li>(a) Transverse process of C7 vertebra</li><li>(b) Ventral ramus of C8 spinal nerve, which passes laterally above the neck of 1st rib</li><li>(c) Neck of 1st rib</li><li>(d) Cupola of cervical pleura</li></ul>
<i>Roof</i>	It is formed by carotid sheath

**FIG. 12.9 ■** Boundaries and contents of right scalenovertbral triangle (triangle of vertebral artery).

### Contents:

1. **First part of vertebral artery and accompanying veins .**  
The artery extends upwards vertically from the base to enter the foramen transversarium of C6 at the apex.
2. **Thyrocervical trunk and inferior thyroid artery ;** the later arches medially across the apical part of the triangle.
3. **Sympathetic chain with stellate ganglion** lies posterolateral to vertebral artery.
4. **Thoracic duct** on the left side arches laterally at the level of transverse process of C7 vertebra.
5. Ansa subclavia.

## N.B.

*Scalenus minimus (pleuralis)*: The scalenus minimus is the fourth rudimentary scalene muscle.

It arises from anterior border of the transverse process of C7 vertebra and inserted to inner border of the 1st rib behind the groove for the subclavian artery and to the dome of the cervical pleura.

The *suprapleural membrane* is regarded as the flattened tendon of this muscle.

The contraction of scalenus minimus pulls up the dome of pleura to make it tense.

## Cervical plexus

### Formation

It is formed by ventral rami of the upper four cervical nerves (C1-C4). The position of rami of cervical spinal nerves in relation to paravertebral muscles is shown in [Figure 12.10](#). The ventral rami of C2–C4 divide into upper and lower branches.

**FIG. 12.10** ■ Position of rami of cervical spinal nerve in relation to prevertebral muscles.

The ventral ramus of C1 and branches of C2–C4 ventral rami are connected with one another to form three loops; hence, cervical plexus is also called **plexus of loops**. The *first loop* is directed forwards in front of the transverse process of atlas and the remaining two loops are directed backwards (Fig. 12.11 ).

**FIG. 12.11 ■** Cervical plexus: A. with loops and cutaneous branches, B. with its communicating branches.

## Position and relations

The cervical plexus lies on levator scapulae and scalenus medius muscles deep to prevertebral fascia, internal jugular vein, and sternocleidomastoid.

## Branches (Figs 12.11 and 12.12 )

The cervical plexus supplies skin and muscles of the neck, and the thoracoabdominal diaphragm. Its branches are arranged into superficial and deep groups.

**Superficial (cutaneous) branches** are as follows:

1. Lesser occipital nerve (C2)
2. Great auricular nerve (C2, C3)
3. Transverse (anterior) cervical nerve (C2, C3)
4. Supraclavicular nerve (C3, C4).

**Deep branches** are as follows:

1. Communicating branches, namely:

- (a) Grey rami communicantes from superior cervical sympathetic ganglion to all the four roots
- (b) A branch of C1 joins the hypoglossal nerve
- (c) A branch from C2 to sternocleidomastoid and branches from C3–C4 to trapezius communicate with spinal accessory nerve

2. **Muscular branches** : The following muscles are supplied by cervical plexus:

- (a) Rectus capitis anterior (C1)
- (b) Rectus capitis lateralis (C1, C2)
- (c) Longus capitis (C1–C3)
- (d) Longus colli (C2–C4)
- (e) Strap muscles (C1–C3)
- (f) Sternocleidomastoid (C2)
- (g) Trapezius (C3, C4)
- (h) Levator scapulae (C3, C4)
- (i) Scalene muscles (C3, C4)
- (j) Diaphragm (C3, C4).

**FIG. 12.12 ■** Phrenic nerve: A. Formation, course and distribution of phrenic nerve proper, B. Accessory phrenic nerve.

## **Ansa cervicalis**

It is a nerve loop in the neck connecting superior root from C1 with inferior root from C2 - C3. It is described in detail on page 92.

## **Phrenic nerve (Fig 12.12 )**

### **Origin**

It arises from ventral rami of C3, C4, and C5 but chiefly from C4. It is formed at the lateral border of scalene anterior at the level of upper border of thyroid cartilage.

### **Course**

It runs vertically downwards on the anterior surface of the scalenus anterior, which it crosses obliquely from lateral to medial side. Then it runs downwards on the cervical pleura behind subclavian vein to enter the thorax behind first costal cartilage.

### **Distribution**

The phrenic nerve is a mixed nerve. It provides:

- (a) Motor supply to the diaphragm (muscle of respiration)
- (b) Sensory innervation to central tendon of diaphragm pericardium, diaphragmatic and mediastinal pleura, and subdiaphragmatic peritoneum.

### **Accessory phrenic nerve**

It is the branch from *nerve to subclavius* containing C5 fibres. It runs lateral to phrenic nerve and descends behind or sometimes in front of the subclavian vein to join the main phrenic nerve usually near the 1st rib but occasionally below the root of the lung.

### **N.B.**

In case of accessory phrenic nerve, the fibres of C5 nerve in spite of joining the phrenic nerve at its commencement runs through, nerve to subclavius and then leaves it as accessory nerve to join the main phrenic nerve at the thoracic inlet.

## **CLINICAL CORRELATION**

**Phrenic crush/avulsion:** Before the advent of modern antitubercular treatment, phrenic crush used to be done to produce paralysis of the corresponding half of the diaphragm in order to provide rest to the diseased lung and thus promote healing.

In *phrenic crush*, the accessory phrenic nerve, if present, should also be crushed; otherwise, C5 fibres will escape and diaphragm will continue to function.

### **Cervical sympathetic trunk/chain (Fig. 12.13 ) AN 35.6**

The two sympathetic trunks (right and left) extend from the base of the skull to the base of coccyx, where they join to form **ganglion impar** .

**FIG. 12.13 ■** Cervical sympathetic trunk and its branches.

The **cervical part of sympathetic trunk/chain**, one on either side of cervical part of the vertebral column lies in front of the transverse processes

of cervical vertebrae and neck of the 1st rib behind the carotid sheaths and in front of prevertebral fascia.

Each trunk is continuous upwards into the cranial cavity as the **internal carotid nerve** accompanying the internal carotid artery. Inferiorly, it becomes continuous with the thoracic part of the sympathetic chain at the neck of the 1st rib.

The cervical part of sympathetic trunk does not receive the preganglionic fibres through white rami communicantes from the cervical segments of the spinal cord, but it does give grey rami communicantes to all the cervical spinal nerves. Each trunk receives preganglionic fibres from lateral horn cells of T1–T4 spinal segments.

### **Cervical sympathetic ganglia**

There are three cervical sympathetic ganglia: superior, middle, and inferior. They are formed by the fusion of eight primitive ganglia, corresponding to eight cervical nerves. The characteristics of these ganglia are as follows:

#### **1. Superior cervical ganglion**

- (a) It is the largest of the cervical sympathetic ganglion.
- (b) It is spindle-shaped and approximately 2.5 cm long.
- (c) It lies just below the skull, in front of transverse processes of C2 and C3 vertebrae, behind the carotid sheath and in front of the prevertebral fascia.
- (d) It is formed by the fusion of four primitive cervical ganglia.

#### **2. Middle cervical ganglion**

- (a) It is very small and often absent.
- (b) It lies in the lower part of the neck, in front of transverse process of C6 just above the inferior thyroid artery.
- (c) It is formed by the fusion of the 5th and 6th primitive cervical ganglia.

#### **3. Inferior cervical ganglion**

- (a) It is formed by the fusion of the 7th and 8th primitive cervical ganglia.
- (b) It is generally fused with the 1st thoracic ganglion to form the **cervicothoracic ganglion** ; it is also called **stellate ganglion** because of its star-shaped appearance.
- (c) It lies between transverse process of C7 and the neck of the rib.

### **Branches**

Each of the three ganglia gives three common types of branches, namely:

1. Grey rami communicantes to cervical nerves
2. A cardiac branch/nerve
3. A branch/branches to form a plexus around an artery.

### Branches of superior ganglion

These are as follows:

1. Grey rami communicantes to ventral rami of upper four cervical nerves
2. Superior cervical cardiac nerve
3. Carotid branches form sympathetic plexus around internal and external carotid arteries

In addition to the above-mentioned branches, superior ganglion also gives rise to a *pharyngeal branch*, which takes part in the formation of pharyngeal plexus of nerves.

### Branches from middle ganglion

These are as follows:

1. Grey rami communicantes to ventral rami of C5 and C6 spinal nerves.
2. Thyroid branches to form a plexus around the inferior thyroid artery.
3. Middle cervical cardiac nerve.

In addition to the above-mentioned branches, the middle cervical ganglion also gives rise to **tracheal and oesophageal branches**.

### Branches from inferior ganglion

These are as follows:

1. Grey rami communicantes to ventral rami of C7 and C8 spinal nerves
2. Inferior cervical cardiac nerve
3. Vertebral and subclavian branches, which form plexus around vertebral and subclavian arteries, respectively

### N. B.

*Ansa subclavia* is a nerve loop around subclavian artery connecting middle

and inferior cervical ganglia.

### **CLINICAL CORRELATION AN 31.3**

**Horner syndrome:** The head and neck region is supplied by the sympathetic fibres, which arise in the upper thoracic spinal segments. These preganglionic fibres pass through stellate ganglion to relay in the superior cervical sympathetic ganglion. The postganglionic fibres arise from cells of this ganglion and supply the structures in the head and neck.

An injury to cervical sympathetic trunk produces a clinical condition called *Horner syndrome*.

Characteristic features (Fig. 12.14 ):

- (a) *Partial ptosis* (partial drooping of upper eyelid), due to paralysis of smooth part of levator palpebrae superioris muscle (Muller's muscle).
- (b) Miosis, that is, constriction of the pupil, due to paralysis of dilator pupillae.
- (c) *Anhydrosis*, that is, loss of sweating on that side of face, due to sudomotor and vasoconstrictor denervation.
- (d) Increased temperature and redness.
- (e) *Enophthalmos*, that is, sunken eyeball, not confirmed by ophthalmometry.
- (f) *Loss of ciliospinal reflex*, that is, pinching the skin of the back of neck does not produce dilation of the pupil, which in healthy person takes place.

**FIG. 12.14 ■** Horner syndrome (left side).

## **Root of the neck**

The root of the neck is defined as the area of the neck immediately above the thoracic inlet. The thoracic inlet is a space bounded by 1st thoracic vertebra, 1st rib, and manubrium sterni. The structures pass both into and out of the thoracic cavity through this space ([Fig. 12.15](#) ).

**FIG. 12.15** ■ Deep structures at the root of the neck.

The clinical importance of this area is that the numerous important structures, such as carotid and subclavian arteries, trachea and oesophagus, and large veins are all packed together into this relatively small space. Therefore, any further decrease in this space may lead to dire consequences. The reduction in space may be caused by a number of clinical conditions such as tumour of apex of lung (**Pancoast tumour** ), enlarged thyroid gland, and cervical rib. The students should read this region very carefully.

The following structures merit description in detail:

1. Scalenovertbral triangle/triangle of vertebral artery (see page 168)
2. Scalene triangle (see page 167)
3. Cervical pleura

## Cervical pleura

The cervical pleura covers the apex of the lung at the root of the neck. It rises

into the root of the neck approximately 3.4 cm above the 1st costal cartilage but not above the neck of the 1st rib because of obliquity of the 1st rib. It rises 2.5 cm above the medial third of the clavicle.

The cervical pleura is strengthened by the suprapleural membrane (also called *Sibson's fascia*) so that the root of the neck is not puffed up and down during respiration.

## Relations

### *Anterior:*

1. Subclavian artery
2. Scalenus anterior

### *Posterior:*

- Neck of 1st rib and structures crossing in front of it

### *Lateral:*

1. Scalenus medius
2. Lower trunk of brachial plexus

### *Medial:*

1. Vertebral bodies
2. Trachea and oesophagus
3. Recurrent laryngeal nerve in the tracheoesophageal groove
4. Thoracic duct on the left side
5. Large blood vessels of the neck.

## **N.B.**

Structures crossing in front of the neck of 1st rib from medial to lateral side are as follows:

- Sympathetic chain
- First posterior intercostal vein
- Superior intercostal artery
- First thoracic nerve (large ascending branch of its ventral ramus).

## **Lymph trunks at the root of the neck**

The lymph from head and neck region is returned to the venous blood via left and right lymph trunks, which converge at the root of neck at the junction of internal jugular and subclavian veins. The various lymph trunks which converge on the right and left side of the root of the neck are as described in

the following text:

**On the right side of neck** , the three trunks that converge are as follows:

1. **Right jugular trunk** extends along the ventrolateral aspect of the internal jugular vein. It drains lymph from right half of the head and neck.
2. **Right subclavian trunk** extends along the axillary and subclavian veins and draws lymph from the right upper limb and superficial tissues of the right half of the thoracoabdominal wall down to the umbilicus anteriorly and iliac crest posteriorly.
3. **Right bronchomediastinal trunk** ascends over the trachea. It drains lymph from right lung, bronchi and trachea, and right half of the mediastinum.

The right jugular and subclavian trunks may unite to form *right lymphatic duct*, which ends in a similar way to that of the thoracic duct.

**On the left side** , the four trunks that converge are as follows:

1. **Left jugular trunk** drains lymph from left half of the head and neck. Its course and termination are similar to that on the right side.
2. **Left subclavian trunk** drains the lymph from the left upper limb and left half of thoracoabdominal wall in the same way as that of right subclavian trunk.
3. **Left bronchomediastinal trunk** is similar to that of the right trunk but drains more of the heart and oesophagus.
4. **Thoracic duct** begins in the abdomen as an upward continuation of cisterna chyli at the lower border of the 12th thoracic vertebra. It enters the thoracic inlet along the left border of the oesophagus. In the neck, it arches laterally at the level of the transverse process of the 7th cervical vertebra.

Its arch rises 3 or 4 cm above the clavicle and curves anteriorly in front of the vertebral system (i.e., vertebral artery and vertebral vein) and left sympathetic trunk and behind the carotid system (i.e., left common carotid artery, left internal jugular vein, and left vagus nerve). Finally, the duct descends in front of the arched (first part) subclavian artery and ends by opening into the junction of the left subclavian and internal jugular veins (Fig. 12.15 ).

### *Relations of the thoracic duct*

◦The relations of the thoracic duct arch in the neck ([Fig. 12.16](#) ) are as follows:

#### **Anterior:**

1. Left common carotid artery
2. Left vagus nerve
3. Left internal jugular vein

#### **Posterior:**

1. Vertebral artery and vein
2. Sympathetic trunk
3. Thyrocervical trunk and its branches
4. Prevertebral fascia
5. Phrenic nerve
6. Scalenus anterior muscle.

◦The thoracic duct is the longest and largest lymphatic trunk in the body. It drains the lymph from whole of the body except the right upper quadrant (for details, see [Chapter 11](#) , Lymphatic System in book *General Anatomy with Systemic Anatomy, Radiological Anatomy, Medical Genetics*, 4ed. by Vishram Singh).

### *Tributaries in the neck*

◦Apart from the tributaries in the thorax and abdomen, the thoracic duct receives the following tributaries in the neck:

1. Left jugular trunk
2. Left subclavian trunk
3. Left bronchomediastinal trunk.

**FIG. 12.16 ■** Transverse section of the root of neck showing relationship of various structures in this region.

### Recurrent laryngeal nerve

It runs on either side in the tracheoesophageal groove.

### Trachea and oesophagus

The trachea extends from the lower border of the cricoid cartilage at the level of the lower border of C6 vertebra to the level of sternal angle at the level of lower border of T4. It can be palpated in the midline just above the jugular notch. This part of trachea is crossed by the isthmus of thyroid gland, inferior thyroid veins, thyroidea ima artery (if present), and jugular venous arch.

The oesophagus begins in the neck just below the cricopharyngeus at the lower border of C6 vertebra. It lies on longus colli muscle behind the trachea. The thoracic duct lies on its left lateral border before arching over the triangle of the vertebral artery on the left side (for details, see *Textbook of Anatomy: Upper limb and Thorax*, 4ed. Vol I, by Vishram Singh, [Ch 24](#), [Fig. 24.2](#) ).

### Brachiocephalic veins

These veins collect blood from head and neck, upper limbs, thoracic wall, and anterior abdominal wall. Each vein is formed by the union of corresponding internal jugular and subclavian veins behind medial end of the clavicle. They

end by joining to form superior vena cava behind lower border of the right first costal cartilage at the margin of the sternum.

The **right brachiocephalic vein** descends almost vertically. In the neck, it lies on the cervical pleura lateral to the brachiocephalic trunk. The phrenic nerve and internal thoracic artery lie posterior to it, whereas sternohyoid and sternothyroid muscles lie anterior to it.

The **left brachiocephalic vein** runs obliquely to pass behind upper part of the manubrium sterni to join right brachiocephalic vein, and is therefore much longer.

Both veins receive the vertebral, highest intercostal, and inferior thyroid veins. The thoracic duct and left superior intercostal vein enter the left vein.

### **Golden Facts to Remember**

• <b>Longest prevertebral muscle</b>	Longus cervicis
• <b>Longest and largest scalene muscle</b>	Scalenus medius
• <b>Scalenus medius arises from transverse processes of all cervical vertebrae except</b>	Transverse process of 1st cervical vertebra
• <b>Key muscle at the root of the neck</b>	Scalenus anterior
• <b>Largest cervical sympathetic ganglion</b>	Superior cervical sympathetic ganglion
• <b>Cervical rib</b>	Enlarged costal element of transverse process of C7 vertebra
• <b>Root of the neck</b>	Area of neck immediately above the thoracic inlet
• <b>Stellate ganglion</b>	Cervicothoracic ganglion (page 170)
• <b>Smallest paravertebral muscle</b>	Scalenus posterior
• <b>Accessory phrenic nerve</b>	A branch of nerve to subclavius containing C5 fibres, which join the main phrenic nerve

### **CLINICAL CASE STUDY**

A 19-year-old dental student complained of pain, tingling, and numbness along the medial side of her right forearm and hand. She also had difficulty

in gripping the instruments firmly by the right hand. The physical examination revealed weak right radial pulse. The examining physician suspected the presence of cervical rib and performed Adson's test, which turned out to be positive. The presence of **cervical rib** was confirmed by plain radiograph. She was diagnosed as a case of **scalene syndrome**. She completely recovered of her symptoms after the surgical removal of the cervical rib.

## Questions

1. What is cervical rib?
2. What are the boundaries of scalene triangle?
3. Name the structures passing through scalene triangle.
4. Mention the cause of symptoms told by the patient.
5. What is Adson's test?
6. What precautions should be taken when cervical rib is removed surgically?

## Answers

1. It is an enlarged costal element of the transverse process of the 7th cervical vertebra.
2. It is a narrow triangular space bounded anteriorly by scalenus anterior, posteriorly by scalenus medius, and inferiorly by the upper surface of the 1st rib.
3. Subclavian artery and lower trunk of the brachial plexus.
4. Compression of lower trunk of brachial plexus (C8 and T1) and subclavian artery.
5. This test is performed to assess the functional status of the arterial supply of the upper limb. The patient sitting on a stool is asked to take a deep breath and at the same time turn his or her face towards the affected side. Now the physician can feel the radial pulse. If the radial pulse becomes feeble or absent, the test is said to be positive.
6. The periosteum of the rib must be removed to prevent regeneration of the rib.

---

# Chapter 13: Oral cavity, teeth and tongue

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the tongue under the following headings: (a) external features, (b) muscles, (c) nerve supply, (d) blood supply, (e) lymphatic drainage, and (f) actions of extrinsic and intrinsic muscles of tongue. **AN 39.1**
- Give the embryological basis of hypoglossal nerve injury. **AN 39.2**
- Give the embryological basis of nerve supply of tongue.
- Describe the microanatomical features of tongue. **AN 43.2**
- Write short notes on: (a) features on the dorsal surface of tongue, (b) features on ventral surface of tongue, (c) papillae of tongue, (d) parts and structure of tooth, and (e) dental formula.
- Describe the development of tongue in brief and correlate the nerve supply of tongue with its development.
- Give the anatomical/embryological basis of: (a) dental caries, (b) tongue tie, (c) poor prognosis of cancer in posterior one-third of tongue, and (d) Ludwig angina.

## Oral cavity

The oral cavity (mouth) is the first part of digestive tube. It extends anteroposteriorly from lips to the oropharyngeal isthmus. It is commonly used for ingestion of food and fluids.

The major structures present in the oral cavity are tongue and teeth.

## Subdivisions

The oral cavity is divided into two parts ([Fig. 13.1](#)):

1. **Vestibule** : It is a smaller slit-like space between lips/cheeks and teeth/gingivae (gums).
2. **Oral cavity proper** : It is a larger space inside the teeth and gums.

**FIG. 13.1** ■ Subdivisions of the oral cavity as seen in its coronal section.

## Vestibule of the mouth

The vestibule of the mouth is a narrow space that lies outside the teeth and gums, and inside the lips and cheeks. It is limited above and below by the reflection of mucous membrane from the lips and cheeks to the gums. When the mouth is open, it freely communicates with the oral cavity proper but when it is closed, that is, when the teeth are occluded, it communicates on each side with the oral cavity proper through a small gap behind the 3rd molar teeth and ramus of the mandible called **retromolar region**. Except teeth, entire vestibule is lined by mucous membrane.

The lateral wall of the vestibule is formed by cheek made up of buccinator muscle. The tone of buccinator muscle and muscles of lips keep the walls of the vestibule in contact with the teeth and gums. In facial palsy, due to paralysis of these muscles, lips and cheeks fall away from teeth and gums,

and food tends to collect in the vestibule of the mouth.

*The openings in the vestibule of the mouth are as follows :*

1. Opening of parotid duct; the parotid duct opens into the vestibule of mouth on a papilla opposite the crown of the upper 2nd molar tooth.
2. Openings of labial and buccal mucous glands.
3. Openings of four or five molar glands (mucus) situated on the buccopharyngeal fascia.

## CLINICAL CORRELATION

- **Parotid papilla:** A small projection in the buccal mucosa adjacent to the 2nd upper molar tooth at the opening of parotid duct in vestibule of mouth. It provides an access to the parotid duct for injection of a radiopaque dye to locate the calculi in the parotid duct system.
- **Koplik spots:** These *pin-point spots* are seen in the mucous membrane of cheek around the opening of parotid duct, before the appearance of rashes of measles.

## Lips

The lips are two mobile musculofibrous folds that surround the opening of the mouth. The upper and lower lips meet laterally at an angle of the mouth, usually in front of 1st premolar tooth.

The lips are lined externally by the skin and internally by the mucous membrane. The red portion of lip anteriorly is lined by thinly keratinized layer of stratified squamous epithelium deeply penetrated by highly vascularized dermal papillae which impart the typical red hue to the lips. It is called **vermillion zone**. The red hue is due to rich vascular bed visible through the thin moist epithelium. The skin and vermillion zone meet at the **vermillion border**.

The internal aspect of each lip is connected to the corresponding gum by a median fold of the mucous membrane called **frenulum of the lip**.

The vermillion border of upper lip looks like a 'cupid's bow'.

## Structure

From superficial to deep, the lip is composed of the following structures:

1. Skin

2. Superficial fascia
3. Orbicularis oris muscle
4. Submucosa containing mucous glands
5. Mucous membrane.

## Blood vessels

Each lip is supplied by labial branches of facial artery. Each lip has an **arterial arch** formed by the end-on anastomosis between labial branches of the facial arteries. When this arterial arch is cut, blood spurts from both ends with equal force. The veins correspond to the arteries and drain into the facial vein.

## Lymphatics

The lymphatics from the central part of the lower lip drain into submental lymph nodes. The lymphatics from lateral parts of lower lip and whole of upper lip drain into submandibular lymph nodes.

## Nerve supply

The lips have rich sensory supply from trigeminal nerve. The upper lip is supplied by labial branches of the infraorbital nerve (a branch of maxillary division) and lower lip by the mental nerve (a branch of mandibular division of the trigeminal nerve). The red portions of lip are highly sensitive and represented by a large area in the sensory cortex of cerebral hemisphere.

## Cheeks

The cheeks are fleshy flaps forming a large part of the face. Each cheek is continuous in front with the lip. The junction between the two is marked by the **nasolabial sulcus** or the nasolabial furrow, which extends from side of the nose to the angle of the mouth. Like lips, the cheeks are lined externally by the skin and internally by the mucous membrane.

## Structure

The cheek is largely composed of buccinator muscle. In addition, it contains buccal glands, blood vessels, and nerves. The buccinator muscle is covered by **buccopharyngeal fascia**. The buccal pad of fat is best developed in infants, overlies the buccopharyngeal fascia and extends posteriorly deep to masseter muscle.

## Layers of the cheek

From superficial to deep, the layers of the cheek are as follows:

1. Skin
2. Superficial fascia containing some muscles of facial expression, namely zygomaticus major and risorius
3. Buccal pad of fat
4. Buccopharyngeal fascia
5. Buccinator muscle between the alveolar processes of both jaws
6. Submucosa containing buccal (mucous) glands
7. Mucous membrane.

The last five layers of the cheek are pierced by the parotid duct. The lymphatics from cheek drain into the submandibular and preauricular lymph nodes.

## Mucous lining of the cheek

The inner aspect of the cheek is lined by stratified squamous epithelium. It is pierced by parotid duct opposite the maxillary 2nd molar tooth at tip of a small **parotid papilla** .

A hyperkeratinized line (the *linea alba* ) may be seen at a position related to the occlusal plane of the teeth.

### CLINICAL CORRELATION

In the **retromolar region** , a fold of mucous membrane containing pterygomandibular raphe extends between the upper and lower alveoli. The entrance to the *pterygomandibular space* , which contains inferior alveolar and lingual nerves, lies lateral to pterygomandibular fold and medial to the ridge produced by site for injection of anaesthetic agent in *inferior alveolar nerve block*.

## Gums (gingiva)

The gums are composed of fibrous tissue covered with a smooth vascular mucous membrane. They envelop the alveolar processes of the jaws and the necks of the teeth. At the necks of the teeth, the fibrous tissue of gum becomes continuous with periodontal membrane, which attaches the teeth to their sockets.

## Parts of gum

The gum/gingiva has three parts, namely

1. **Free part (free gingiva)** , which surrounds the neck of tooth like a collar.
2. **Attached part (attached gingiva)** , which is firmly attached to the alveolar process.
3. **Interdental part (interdental gingiva)** , which is extension of the attached gingiva between the teeth.

## Nerve supply

- The gingiva associated with upper teeth is supplied by the branches of maxillary nerve.
- The gingiva associated with lower teeth is supplied by the branches of mandibular nerve.

*Upper gum (gingiva) on :*

- (a) The labial (buccal) aspect of upper teeth is supplied by the posterior, middle, and anterior-superior alveolar nerves
- (b) The lingual (palatal) aspect of upper teeth is supplied by the greater palatine and nasopalatine nerves.

## N.B.

- (1) *Greater palatine nerve* supplies gingiva (gum) associated premolar and molar teeth.
- (2) *Nasopalatine nerve* supplies gingiva (gum) associated with incisor and canine teeth.

*Lower gums (gingiva) on :*

- (a) The labial (buccal) aspect of lower teeth is supplied by buccal branch of mandibular nerve, and incisive branch of mental nerve
- (b) The lingual aspect of lower teeth is supplied by the lingual nerve.

## Lymphatic drainage

**Upper gums:** The lymphatics from upper gums drain into submandibular lymph nodes.

**Lower gums:** The lymphatics from anterior part (i.e., gums of lower central incisors) drain into submental lymph nodes, whereas those from remaining part drain into submandibular lymph nodes.

## CLINICAL CORRELATION

- **Gingivitis:** The improper oral hygiene may cause inflammation of gums (*gingivitis*) and suppuration with formation of pockets of pus between teeth and gums leading to clinical condition called *pyorrhoea*, which clinically present as: (1) discharge of pus at the margins of gums and (2) foul smell during breathing.
- **Scurvy:** In *scurvy* due to deficiency of vitamin C, the gums become swollen, spongy, and bleed on touch.

## Teeth

The teeth are mineralized bone-like structures projecting from the alveolar processes of the jaws.

### Functions of teeth

The functions of teeth are as follows:

1. Incise and grind the food material during mastication
2. Perform (sometimes) the role of weapon for defence or attack
3. Provide beauty to the face and means for facial expression.

### N.B.

The study of teeth, strictly speaking, forms the subject of *odontology*, whereas the science concerned with the diagnosis and treatment of diseases of the teeth and associated structures is called *dentistry* (Latin, *dens*, *dentis* = tooth).

### Number of teeth

In an adult, there are 16 permanent teeth in each jaw.

The humans are **diphyodont**, that is, two sets of teeth develop in a person's lifetime. The first set of teeth is **primary or deciduous teeth**. They begin to form prenatally approximately 14 weeks in intrauterine life and completed postnatally at approximately 3 years of age. The deciduous teeth

remain intact up to approximately 6 years of age. At about that time, **permanent teeth** begin to erupt in the mouth.

The first of milk teeth (lower central incisors) erupt approximately 6 months after birth and the last (2nd milk molars) at approximately 2 years. The first permanent tooth (1st molar) erupts at approximately 6 years and continues until approximately 17 years of age. The wisdom teeth are less predictable and if they do erupt, it is between the ages 17 and 25. Because jaws are formed by this time and other teeth have already well occupied their place, the eruption of wisdom teeth may fail to occur properly causing a clinical condition called **impaction of tooth** .

### **Eruption of teeth**

Most of the teeth in an adult are **successional** , that is, they have succeeded a corresponding milk teeth/primary teeth predecessors. The permanent molars, however, are **accessional** because they have no corresponding milk teeth/primary teeth predecessors. They have been added later on.

### **Eruption of deciduous teeth (Fig. 13.2 A)**

The deciduous teeth begin to erupt at **approximately 6 months** and all are erupted by the end of 2nd year (or soon after).

**FIG. 13.2 ■** Schematic diagram showing approximate age of eruption of teeth: ( **A** ) deciduous teeth; ( **B** ) permanent teeth. The teeth are numbered according to Zsigmondy system.

The teeth of lower jaw erupt somewhat before the corresponding teeth in the upper jaw.

The approximate **age of eruption** of deciduous teeth is as follows (Fig. 13.2 A):

- Lower central incisors: 6 months
- Upper central incisors: 7 months
- Lateral incisors: 8–9 months
- First molar: 12 months (1 year)
- Canines: 18 months (1 year 6 months)
- Second molars: 24 months (2 years).

**Eruption of permanent teeth (Fig. 13.2 B)**

The permanent teeth begin to erupt at approximately 6 years and all get erupted by 18–24 years. The approximate age of eruption of permanent teeth is as follows:

- First molar: 6 years
- Medial incisors: 7 years
- Lateral incisors: 8 years
- First premolar: 9 years
- Second premolar: 10 years
- Canines: 11 years
- Second molars: 12 years
- Third molar (wisdom tooth): 18–24 years.

## CLINICAL CORRELATION

- **Medicolegal significance of eruption of teeth:** The time of eruption of the teeth is a useful stepping stone in a child's development. The time of eruption is also important in forensic medicine to estimate the age at the time of death from the skeletonized remains as a rough guide. The time of eruption of teeth can be thought of in '6' or multiples of '6' as follows:
  - First lower deciduous incisor appears at: 6 months
  - All the deciduous teeth complete eruption by: 24 months
  - Permanent 1st molar appears at: 6 years
  - Permanent 1st incisor appears at: 6 years
  - Permanent 2nd molar appears at: 12 years
  - Permanent 3rd molar appears at: 18–24 years
- **Impaction of tooth:** The 3rd molar tooth erupts between 18 and 21 years and often called as a **wisdom tooth**.
  - It often fails to erupt completely or partially from the gum, leading to a clinical condition called **impaction of tooth**.
  - In recent times, incidence of impaction of tooth has increased due to small size of mandible and maxillae. This is because modern diet is relatively soft, and hence jaws do not offer a good effort in mastication, leading to their reduced size.

## Parts of a tooth (Fig. 13.3)

Each tooth consists of the following three parts:

1. A **crown** , the *anatomical crown* is the part of a tooth that is covered by enamel, whereas *clinical crown* is the part that projects into the oral cavity.
2. A **root** , which is embedded within the socket of jaw beneath the gum.
3. A **neck** , which is the constricted part of the tooth between the crown and root. It is encircled by the gum.

**FIG. 13.3 ■** Parts of the tooth: ( **A** ) extracted upper right canine tooth; ( **B** ) clinical and anatomical crowns.

### Structure of tooth (Fig. 13.4 )

Each tooth is composed of a specialized connective tissue. It essentially consists of a pulp covered by three calcified tissues: dentine, enamel, and cementum.

1. **Pulp** : It is the **inner core** containing soft tissue, blood vessels, nerve, and lymphatics. The pulp is covered by a layer of tall columnar cells called **odontoblasts** . The space within tooth containing pulp is

called **pulp cavity** .

2. **Dentine** : It is a **calcified material** surrounding the pulp cavity. It forms the basis of the tooth and contains **spiral tubules** radiating from the pulp cavity. Each tubule is occupied by a protoplasmic process from the odontoblast. In dentine, the **calcium** and **organic matter** are in same proportion as the bone.
3. **Enamel** : It is the **densely calcified white material** covering the crown of the tooth. It is the **hardest** substance in the body and is made up of **crystalline prisms** . The prisms lie at right angle to the surface of the tooth.
4. **Cement** : It is the **bony covering** over the neck and root of the tooth. It commonly overlaps the lower part of the enamel.
5. **Periodontal membrane** : It is present between the cementum and the socket, both of which act as periosteum. It holds the tooth in the socket and therefore, often termed **periodontal ligament** .

**FIG. 13.4 ■** Structure of the tooth.

### CLINICAL CORRELATION

- **Medicolegal importance of teeth:** The teeth are the hardest and chemically most stable tissue in the body. They can survive extreme environmental conditions. Hence, they are prevented from decay and found intact or fossilized after death for medicolegal purpose to identify the unrecognizable dead bodies.
- **Eye tooth:** The upper canine tooth is often referred to as *eye tooth* because sometimes its long root may extend up to the medial angle of the eye. The infection from its root may reach the facial vein, which may lead to *cavernous sinus thrombosis*.

### Nerve supply (Fig. 13.5 )

The **upper teeth** are supplied by the **posterior, middle,** and **anterior-superior alveolar nerves**, which form a plexus above the apices of the teeth, called *superior dental plexus*.

The **lower teeth** are supplied by the **inferior alveolar (dental) nerve**. The molars and premolars are supplied by the main trunk, whereas canine and incisors by its incisive branch.

**FIG. 13.5** ■ Nerve supply of the teeth. L, lingual nerve.

## CLINICAL CORRELATION

- **Dental anaesthesia:** It is required to carry out various dental procedures.
  - ❖ (a) **Anaesthesia of upper teeth:** Alveolar bone of the maxilla is relatively porous; hence, anaesthetic solution deposited in the gingivae opposite a root of tooth will readily penetrate the bone to anaesthetize the tooth to carry out dental procedures.
    - ❑ The upper teeth need separate injection to infiltrate anaesthetic agent on both buccal and palatal surfaces of alveolar process of maxilla.
    - ❑ Infiltration on buccal aspect is sufficient for painless drilling of the tooth, but for extraction of tooth, the palatal aspect must be infiltrated as well.
  - ❖ (b) **Anaesthesia of lower teeth:** The infiltration anaesthesia is

usually effective for the incisor teeth only. The infiltration anaesthesia does not work for other mandibular teeth because they are embedded in the bone, which is dense, hence does not allow the sufficient penetration of anaesthetic agent. Therefore, for those teeth, the *inferior alveolar nerve block* is required.

- **Dental caries:** The decay or formation of cavities in teeth due to destruction or decalcification of enamel and dentine due to acid produced by bacteria from food debris on tooth surface.
- **Notching of upper permanent incisors:** This is often seen in rickets associated with irregular dentition. The notching corresponds to a small segment of a large circle.

## Arterial supply

The **upper teeth** are supplied by **posterior, middle, and anterior-superior alveolar arteries** which are branches of the maxillary artery.

The **lower teeth** are supplied by the **inferior alveolar (dental) artery**, a branch of first part of maxillary artery.

## N.B.

- The blood vessels and nerves enter the pulp cavity of the tooth through apical foramen.
- The pulp and periodontal membrane have the same nerve supply but is different from that of the overlying gum.

## Lymphatic drainage

The lymph from teeth is usually drained into ipsilateral submandibular lymph nodes. Lymph from the mandibular incisors, however, drains into submental lymph nodes.

## CLINICAL CORRELATION

**Sometimes extraction of tooth may lead to osteomyelitis (inflammation of the bone) of the jaw:** It usually occurs in the lower jaw and not in the upper jaw. This is because the lower jaw is supplied only by a single inferior alveolar artery. Therefore, damage of this artery at extraction produces bone necrosis.

The upper jaw on the contrary receives segmental supply by three arteries: posterior, middle, and anterior-superior alveolar arteries. Therefore, ischaemia does not occur following injury to an individual artery.

### Types of teeth (Fig. 13.6 )

The human beings have **heterodont dentition** , that is, the teeth vary structurally and are adapted to handle food in different ways. The teeth are, therefore, classified as incisors, canines, premolars, and molars.

**FIG. 13.6** ■ Types of the permanent teeth (upper and lower teeth) of the right side.

### Incisors

They are **four in each jaw** , two on each side of the median plane. They are arranged in two groups: two medial incisors and two lateral incisors.

The four upper incisors are carried by the premaxillary portion of the maxilla. As the name suggests, the incisors cut the food by their cutting edges. They are chisel like. The upper and lower incisors do not meet edge to edge but by a sliding overlap like the blades of a pair of scissors.

## Canines

There are **two canines on each jaw** , one on each side, lateral to the incisors. They are so named because they are prominent in dogs (carnivorous animals). The canines are holding and tearing teeth with conical and rugged crowns. They are sometimes referred to as **cuspid**s (or **eye teeth** ). They are long teeth and usually the **last deciduous teeth to be lost** .

## Premolars

There are **four premolars in each jaw** , two on each side. The premolars assist in crushing the food. They have two cusps and are therefore also called **bicuspid teeth** .

## Molars

There are **six molars** (Latin, *molar* = grinder) in each jaw, three on each side. They crush and grind the food. They possess three to five tubercles, that is, cusps on their crowns. Usually, upper molars have four and lower molars have five cusps on their crown.

### N.B.

- The 1st premolars are usually the largest teeth.
- The 3rd molar is often known as the *wisdom tooth* . Nowadays, they may be lacking or impacted.
- The permanent molars have no deciduous predecessors.

## Number of roots in different types of teeth

The different types of teeth and number of their roots are enumerated in [Table 13.1](#) .

### **TABLE 13.1**

#### Number of roots in all types of teeth

Teeth	Number of roots
<ul style="list-style-type: none"><li>• Upper molars</li><li>• Lower molars</li></ul>	3 roots each (2 lateral and 1 medial) 2 roots each (1 anterior and 1

All other teeth except 1st upper premolar*	posterior) 1 root
--	----------------------

\* First upper premolar usually has a bifid root.

## CLINICAL CORRELATION

The teeth can be distinguished from one another by the characteristics of their roots and crowns.

### Dental formula

A dental formula is a graphic representation of the types, number, and position of teeth in the oral cavity. The humans being heterodont, the dental formulae for deciduous and permanent teeth are as follows:

#### Dental formula for deciduous teeth

$$\frac{I2/2, C1/1, M2/2}{I2/2, C1/1, M2/2} = 20 \text{ teeth}$$

#### Dental formula for permanent teeth

$$\frac{I2/2, C1/1, P2/2, M3/3}{I2/2, C1/1, P2/2, M3/3} = 32 \text{ teeth}$$

I, incisor; C, canine; P, premolar; M, molar

### Clinical notation system (Fig. 13.2 )

In clinical practice, dental doctors follow a definite system to note various teeth. There are many systems. As an example, one of the systems called *Zsigmondy numbering system* is given as follows. For details of other system, consult dental anatomy books.

### Permanent teeth

They are identified by assigning a number from 1 to 8 from anterior to posterior in each quadrant, namely, central incisor = 1, lateral incisor = 2, canine = 3, first premolar = 4, second premolar = 5, first molar = 6, second molar = 7, and third molar = 8 (Fig. 13.7 ).

**FIG. 13.7** ■ Dental terminology used for surfaces. 1, central incisor; 2, lateral incisor; 3, canine; 4, 1st premolar; 5, 2nd premolar; 6, 1st molar; 7, 2nd molar; 8, 3rd molar.

The quadrant symbols are as follows:

Maxillary right =

Maxillary left =

Mandibular right =

Mandibular left =

The complete set of permanent teeth in all quadrants is noted as follows:

Maxillary right quadrant	Maxillary left quadrant
8 7 6 5 4 3 2 1	1 2 3 4 5 6 7 8
8 7 6 5 4 3 2 1	1 2 3 4 5 6 7 8
Mandibular right quadrant	Mandibular left quadrant

## Deciduous (primary) teeth

They are identified by assigning letters from A to E, from anterior to posterior in each quadrant, namely, central incisor = A, lateral incisor = B, canine = C, first molar = D, and second molar = E.

The complete set of deciduous teeth is noted as follows:

Maxillary right quadrant	Maxillary left quadrant
EDCBA	ABCDE
EDCBA	ABCDE
Mandibular right quadrant	Mandibular left quadrant

## Variations in number of teeth

The variation in number of teeth is rare in deciduous teeth but not uncommon in permanent teeth. One or more teeth may fail to develop, the condition is called **hypodontia** . Conversely, additional or supernumerary teeth may develop producing a condition called **hyperdontia** .

### N.B.

The 3rd permanent molar is the most frequently missing tooth in most of the races.

## Dental terminology

### Special terms used to describe the surfaces of teeth (Fig. 13.6 )

The surfaces named according to their position:

- For incisors and canines, the surfaces towards the lips are called **labial surfaces** .
- For premolars and molars, the surfaces towards the cheek are called **buccal surfaces** .

### N.B.

- All labial and buccal surfaces are collectively called *facial surfaces* .
- The surfaces of upper jaw teeth facing palate are called *palatal surfaces*.
- The surfaces of lower jaw teeth facing tongue are called *lingual surfaces*.

- The surfaces of all the teeth towards the midline are called *medial surfaces*.
- The surfaces of all teeth away from the midline are called *distal surfaces*.
- The surfaces of incisors and canines that come in contact for cutting are called *incisive surfaces* .
- The surfaces of premolars and molars that come in contact for grinding and crushing are called *occlusal surfaces*.

### Terms used to describe the ridges of teeth

Their description is beyond the scope of this book. (For details, consult dental anatomy books.)

The central and lateral incisors and canines as a group are called **anterior teeth** , whereas premolars and molars as a group are called **posterior teeth** .

### Development of the teeth (Fig. 13.8 )

The teeth develop from **ectoderm** and an underlying layer of **neural crest cells** .

**FIG. 13.8 ■ ( A ) Development of teeth; ( B ) Eruption of tooth.** The figures in the inset show formation of dental lamina (a), and tooth buds of all deciduous teeth (b).

The four broad stages in the development of teeth are as follows:

- 1. Dental lamina stage:** The oral epithelium (ectoderm) along the alveolar process thickens to form the **dental lamina** , which proliferates at various sites to form downgrowths called **tooth buds (enamel organs)** .
- 2. Bud stage:** The **enamel organs** develop buds first for 20 deciduous teeth and then for permanent teeth. They give rise to **ameloblasts** , which produce enamel.

3. **Cap stage:** The underlying neural crest cells proliferate to form **dental papilla**, which is covered by the bottom of enamel organ like a cap. This stage of development is called **cap stage**. The dental papilla gives rise to the **odontoblasts**, which produce dentine and pulp.
4. **Bell stage:** As the dental papilla further grows, it invaginates the enamel organ. The surface layers of dental papilla condense to form **dental sac**, which surrounds the enamel organ. This stage of development is called **bell stage**. The dental sac gives rise to **cementoblasts** (which produce cementum) and **periodontal ligaments**. The rest of the neural crest cells form the **pulp of the tooth**.

Thus, the tissues of tooth are derived from two embryological sources. These are summarized in [Table 13.2](#).

 **TABLE 13.2**

### Origin of various tissues of tooth

Ectoderm	Neural crest cells
Enamel	<ul style="list-style-type: none"> <li>• Dentine</li> <li>• Dental pulp</li> <li>• Cementum</li> <li>• Periodontal ligaments</li> </ul>

### Eruption of tooth

It is a process in tooth development in which teeth erupt from alveoli and enter the mouth and become visible. The mechanism of eruption depends on correlation between space in the course of eruption and eruption pressure provided by apical root membrane and ability of periodontal ligament to adapt to eruptive movements. Basically tooth eruption involves bone remodelling mechanisms.

### **CLINICAL CORRELATION**

The irregular dentition is common in children suffering from rickets and often associated with notching of upper permanent incisors.

## Oral cavity proper

### Boundaries

The oral cavity proper has a roof and a floor. *Posteriorly*, the oral cavity communicates with the oropharynx through **oropharyngeal isthmus** (also called *isthmus of fauces* ), which is bounded superiorly by the soft palate, inferiorly by the tongue and on each side by the palatoglossal arches. The approximation of these arches shuts off the mouth from oropharynx and is essential to deglutition (Fig. 13.9 ).

**FIG. 13.9** ■ The fauces and its isthmus seen through the widely open mouth.

### Floor of the mouth

The floor of the mouth is a small horseshoe-shaped region situated beneath the anterior two-third of the tongue and above the muscular diaphragm

formed by **two mylohyoid muscles** . The surface of the floor is formed by mucous membrane, which connects the tongue to the mandible. Laterally, the mucous membrane passes from the side of the tongue onto the mandible.

Anteriorly, the mucous membrane stretches from one-half of the mandible to the other. The anterior part of the floor is called **sublingual region** , which intervenes between the ventral surface of the anterior two-third of the tongue and the floor of the mouth.

The sublingual region presents the following features ([Fig. 13.10](#) ):

1. The lower surface of the tongue is connected to the floor of the mouth by a median fold of the mucous membrane called **frenulum linguae** .
2. On each side of the lower end of frenulum, there is an elevation called **sublingual papilla** , on the summit of which opens the submandibular duct.
3. The sublingual gland projects up into the floor of the mouth and produces an elevation in the mucous membrane on each side of the frenulum called **sublingual fold** . Most of the sublingual ducts open on this fold.

**FIG. 13.10** ■ Sublingual region seen when the tongue is turned upwards. Features on inferior surface of the tongue are also seen.

Many structures in the oral cavity are termed by their relationship to the tongue, palate, cheeks, and lips (Fig. 13.10). The structures closest to the tongue are termed **lingual**, those closest to palate **palatal**, those closest to cheeks **buccal**, and those closest to lips **labial**.

### CLINICAL CORRELATION

**Ludwig angina** is a cellulitis of the floor of the mouth, usually due to infection from a carious molar tooth, causing inflammatory oedema of the floor of the mouth. It spreads to the submandibular and submental regions producing diffuse swelling in these regions also. The tongue is pushed upwards because of oedema of the floor of the mouth, resulting in difficulty in swallowing.

### Roof of the mouth

The roof of the mouth is formed by palate. The anterior two-third of palate, made up of bones is called **hard palate** , whereas posterior one-third made of soft issue is called **soft palate** . From the posterior free margin of the soft palate, a small conical projection called **uvula** hangs down in the median region. A poorly marked median raphe extends from uvula to the **incisive papilla** – a slight elevation behind the incisive fossa.

The mucous membrane in the anterior part of the hard palate is thrown into three or four **transverse palatine folds** but posteriorly it is comparatively smooth. The palate is described in detail with pharynx in [Chapter 14](#) .

## Tongue AN 39.1

The tongue is a mobile muscular organ in the oral cavity, which bulges upwards from the floor of the mouth and its posterior part forms the anterior wall of the oropharynx.

It is essentially a mass of skeletal muscle covered by mucous membrane. The muscle mass is separated into right and left halves by a midline fibrous septum. The tongue is separated from teeth by a deep **alveololingual sulcus** , which is filled in by palatoglossal fold/arch posterior to the last molar tooth.

The dorsal aspect of tongue is studded with tiny bumps – the papillae giving it a rough texture. The surface of papillae contains thousands of taste buds.

### Functions

The tongue performs the following functions:

1. Taste
2. Speech
3. Mastication
4. Deglutition.

### Shape

The tongue is conical in shape being elongated posteroanteriorly and flattened dorsoventrally.

### External features

The tongue exhibits the following external features:

1. A root
2. A tip
3. A body.

### Root

The root of the tongue is attached to the mandible and hyoid bone by muscles. It is because of these attachments that the tongue is not swallowed during deglutition. The nerve and vessels of the tongue enter through its root.

### Tip

It is the anterior free end of the tongue, which comes into contact with the central incisors.

### Body

The bulk of tongue between the root and tip is called *body* . It has dorsal and ventral surfaces and right and left lateral margins.

### N. B.

The posteriormost part of tongue is attached to the epiglottis by 3 folds, viz. median glossoepiglottic fold; and right and left lateral glossoepiglottic folds. The shallow depressions one on either side of median glossoepiglottic fold are called valleculae ([Fig. 13.11](#) ).

### Microanatomical features of tongue AN 43.2

The tongue is basically made up interlacing skeletal muscles fibres and connective tissue with some serous and mucous glands. It is covered by mucosa. The mucosa covering the dorsal surface of tongue is lined by stratified squamous para-keratinized epithelium (masticatory mucosa). It is thrown into number of projections – the **lingual papillae** .

### Dorsal surface of tongue ([Fig. 13.11](#) )

The dorsal surface is convex on all the sides. It is divided by a V-shaped sulcus, the **sulcus terminalis** into two parts, namely:

1. Anterior two-third or **oral part**
2. Posterior one-third or **pharyngeal part** .

**FIG. 13.11** ■ Features on the dorsal surface of the tongue.

The apex of the sulcus terminalis is marked by a blind foramen, the **foramen caecum**, which indicates the point of origin of the median thyroid diverticulum (thyroglossal duct) in the embryonic life.

The features differ markedly in the oral and pharyngeal parts.

The **oral part** presents the following features:

1. A median furrow, representing the bilateral origin of the tongue
2. Large number of papillae.

The **pharyngeal part** presents the following features:

1. Large number of lymphoid follicles, which together constitute the **lingual tonsil**
2. Large number of mucous and serous glands.

### **N.B.**

The oral and pharyngeal parts of the tongue are different in their embryological origin for mucosa of oral two-third develops from the 1st and 2nd pharyngeal arches, whereas that of pharyngeal part develops from the

3rd pharyngeal arches.

## Oral part

The dorsum of oral part presents a shallow median furrow/groove. The mucous membrane is moist and pink and appears velvety because of the presence of numerous papillae.

## CLINICAL CORRELATION

The furring or coating of tongue bears no relation to digestive disturbances as generally thought, but is usually due to smoking, respiratory tract infection, fever, or oral infection.

## Papillae of the tongue (lingual papillae)

They are projections of lamina propria (corium) of mucous membrane covered with epithelium (Figs 13.11 and 13.12 ). The following four chief types of papillae are found:

1. **Vallate papillae:** The vallate papillae (known formerly as *circumvallate papillae* ) are largest (1–2 mm in diameter) and vary in number from 8 to 12 and are arranged in a V-shaped row in front of **sulcus terminalis** . Each papilla is like a truncated cone surrounded by a circular sulcus, which is bounded on its periphery by a wall or **vallum** . The duct of serous glands open into the sulcus (moat) and taste buds are found in the papilla and its vallum.
2. **Filiform papillae:** These are narrowest and most numerous. They are minute conical projections with sharply pointed tips. Filiform papillae are located abundantly on the dorsum of tongue and are largely responsible for its velvety appearance.
3. **Fungiform papillae:** They have a red rounded head (approximately 1 mm in diameter) and a narrower base, mostly at the apex and margins of the tongue, whereas some are scattered over the dorsum of the tongue. They are visible as discrete pink pinheads.
4. **Foliate papillae:** They consist of inconstant vertical grooves and ridges near the margin in front of sulcus terminalis. Foliate papillae are more prominent in the tongue of rabbits. They are rudimentary in humans.

## N.B.

Another type of papillae, called *papillae simplex*, are known. These are surface projections and can be seen only under the microscope.

**FIG. 13.12** ■ Characteristic features of different types of lingual papillae: ( **A** ) filiform; ( **B** ) fungiform; and ( **C** ) vallate.

## Pharyngeal part

The dorsum of pharyngeal part faces posteriorly and forms the base of tongue.

*The base of tongue constitutes anterior wall of the oropharynx and can be inspected only by the use of a mirror or by a downward pressure on the tongue with a tongue spatula.*

The mucous membrane over the dorsum of pharyngeal part is devoid of papillae. It, however, appears uneven because of the presence of numerous lymphatic follicles in the underlying submucosa. These follicles are collectively termed **lingual tonsil**.

The mucous membrane in this part is continuous with mucous membrane covering the palatine tonsils and the pharynx. Posteriorly, it is reflected onto the front of the epiglottis as the median **glossoepiglottic fold** and onto the

lateral wall of pharynx as **lateral glossoepiglottic folds** . The space on each side of the median glossoepiglottic fold is termed **epiglottic vallecula** .

### **Ventral (inferior) surface of the tongue (Fig. 13.13 )**

The inferior surface of tongue is situated in the oral cavity only. The mucous membrane lining this surface is thin, smooth, and purplish. It is reflected onto the floor of the mouth.

The under aspect of the tongue presents the following features:

1. **Frenulum linguae** , a median fold of mucous membrane connecting the undersurface of tongue to the floor of the mouth.
2. **Deep lingual veins** , may be seen through mucous membrane on either side of frenulum linguae (the lingual nerve and lingual artery are medial to the vein but not visible).
3. **Plica fimbriata** , a fringed fimbriated fold of mucous membrane lateral to the lingual vein directed forwards and medially towards the tip of the tongue.

**FIG. 13.13** ■ Features on the ventral (inferior) surface of the tongue and floor of the mouth.

## CLINICAL CORRELATION

- **Tongue tie:** If frenulum extends too far towards the tip of the tongue, it is called *tongue tie*. It inhibits normal movements of the tongue and may interfere with normal speech. This can be corrected by cutting the frenulum surgically.
- Certain drugs, which are lipid soluble can diffuse through thin mucous membrane lining the sublingual region of oral cavity and can be quickly absorbed into the circulation.
  - ✧ A leading example is nitroglycerin (sorbitrate), a vasodilator used in cases of *angina pectoris*. The drug (tablet) is placed under the tongue, where in less than 1 min, it dissolves and passes through the thin oral mucosa into the lingual veins.

- **Carcinoma of the tongue:** The tongue is a common site of carcinoma. It mostly involves lateral margins of anterior two-thirds of the tongue. The relative frequency of various sites of involvement is as follows:
  - *Anterior two-thirds:* 64% (lateral margin, 47%; ventral surface and frenulum linguae, 9%; dorsum, 6.5%; tip, 11.5%)
  - *Posterior one-third:* 20%
  - *Posterior-most (faciolingual) part:* 6%.

## **Muscles of the tongue AN 39.1**

The musculature of tongue consists of extrinsic and intrinsic muscles. The intrinsic muscles are within the tongue and have no attachment outside the tongue, whereas extrinsic muscles take origin from structures outside the tongue and enter the tongue to be inserted in it. The intrinsic muscles change the shape of tongue, whereas extrinsic muscles move the tongue (e.g., protrusion, retraction, and side-to-side movements) as well as alter its shape.

The tongue is divided into symmetrical right and left halves by a medial fibrous septum, which separates the muscles of two sides. Each half of the tongue contains four intrinsic and four extrinsic muscles. These are as follows:

### **Intrinsic muscles**

1. Superior longitudinal
2. Inferior longitudinal
3. Transverse
4. Vertical.

### **Extrinsic muscles**

1. Genioglossus
2. Hyoglossus
3. Styloglossus
4. Palatoglossus.

### **Intrinsic muscles (Fig. 13.14 )**

They are confined to the tongue and are not attached to the bone. They occupy upper part of the tongue and alter its shape. The intrinsic muscles are arranged in several planes. They run in three directions: longitudinal, horizontal, and vertical. The complex interlacing of fibres of these muscles is

responsible for the astonishing way in which the tongue can change its shape, becoming wide and flat, narrow and thick or rolled up laterally to become gutter shaped. The latter shape cannot be achieved by a small number of people and this inability is genetically determined. Intrinsic muscles occupy upper part of the tongue and are attached to the submucous fibrous layer and to the median fibrous septum. Their location and actions are enumerated in Table 13.3 .

**FIG. 13.14 ■** Coronal section of the tongue showing arrangement of intrinsic and extrinsic muscles of the tongue.

**TABLE 13.3**

**Location and actions of intrinsic muscles**

Intrinsic muscle	Location	Actions
<i>Superior longitudinal</i>	Beneath the mucous membrane	<ul style="list-style-type: none"> <li>• Shortens the tongue</li> </ul>

		<ul style="list-style-type: none"> <li>• Makes the dorsum concave</li> </ul>
<b>Inferior longitudinal</b>	Close to inferior surface between genioglossus and hyoglossus	<ul style="list-style-type: none"> <li>• Shortens the tongue</li> <li>• Makes the dorsum convex</li> </ul>
<b>Transverse</b>	Extends from median septum to the margin	Makes the tongue narrow and elongated
<b>Vertical</b>	At the border of the anterior part of the tongue	Makes the tongue broad and flattened

### Extrinsic muscles (Fig. 13.15 )

They attach the tongue to the mandible (genioglossus), the hyoid (hyoglossus), the styloid process (styloglossus), and the palate (palatoglossus) on each side. They are described in detail in submandibular region ([Chapter 9](#) ). Summary of their origin, insertion, and actions is presented in [Table 13.4](#) .

**FIG. 13.15 ■** Extrinsic muscles of the tongue.

**TABLE 13.4**

**Origin, insertion, and actions of extrinsic muscles**

<b>Muscle</b>	<b>Origin</b>	<b>Insertion</b>	<b>Actions</b>
<b><i>Genioglossus</i></b> (a fan-shaped muscle)	Superior genial tubercle	<ul style="list-style-type: none"> <li>• Whole of the tongue (fibres radiate from the tip to the base)</li> <li>• Hyoid bone (lowest fibres)</li> </ul>	Protrudes the tongue when acting together with its counterpart of opposite side
<b><i>Hyoglossus</i></b> (a flat quadrilateral muscle)	Greater cornu and adjacent part of the body of hyoid	Side of tongue (posterior half) between styloglossus laterally and inferior longitudinal muscle medially	<ul style="list-style-type: none"> <li>• Depresses the sides of the tongue</li> <li>• Makes the dorsal surface convex</li> </ul>
<b><i>Styloglossus</i></b> (an elongated slip)	Tip of styloid process and adjacent part of the stylohyoid ligament	Side of tongue (whole length), interdigitating posteriorly with the fibres of hyoglossus	Draws the side of the tongue upwards and backwards
<b><i>Palatoglossus</i></b> (a slender slip)	Oral surface of palatine aponeurosis of palate	Side of tongue (at the junction of its oral and pharyngeal parts)	<ul style="list-style-type: none"> <li>• Pulls up the root of the tongue</li> <li>• Approximates palatoglossal arches</li> </ul>

**Movements of the tongue (Fig. 13.16 )**

The movements of tongue and muscles producing them are listed in Table 13.5 .

**FIG. 13.16 ■** Movements of the tongue: ( **A** ) protrusion of the tongue; ( **B** ) elevation, depression, and retraction.

**TABLE 13.5**

**Movements of the tongue and muscles producing them**

--

<b>Movements of tongue</b> (most important movement)	<b>Muscles</b> Genioglossus muscles (of both sides acting together)
<b>Retraction</b>	Styloglossus muscles (of both sides acting together)
<b>Depression</b>	Hyoglossus muscles (of both sides acting together)
<b>Elevation</b> (of posterior one-third)	Palatoglossus muscles (of both sides acting together)
<b>Changes in shape</b>	Intrinsic muscles

## CLINICAL CORRELATION AN 39.2

- **Safety muscle of tongue:** The genioglossus is called *safety muscle of the tongue*, because two genioglossi form bulk of the tongue and are responsible for protrusion of the tongue. If these muscles are paralysed, the tongue will fall back into the oropharynx and obstruct the air passage causing choking and death. For the same reason during anaesthesia, the tongue is pulled forwards to clear the air passage.
- **Clinical testing of the hypoglossal nerve:** The genioglossi are commonly used for clinical testing of the hypoglossal nerve. The muscles of both sides acting together protrude the tongue ([Fig. 13.6 A](#)), whereas single muscle deviate the tongue to the opposite side. Therefore, when the patient is asked to protrude his or her tongue, the tongue deviates to the paralysed side (i.e., the side of lesion of the hypoglossal nerve; [Fig. 13.17](#)). For details, see page 340.

**FIG. 13.17** ■ Effect of paralysis of the hypoglossal nerve.

( **A** ) Paralysis of the genioglossus on the left side. ( **B** ) Deviation of the tongue on the left side, that is, on the paralysed side.

### Arterial supply (Fig. 13.18 ) AN 39.1

The tongue is supplied by the following arteries:

1. Branches of lingual artery (chief artery of tongue); the deep lingual arteries to the anterior part and dorsal lingual arteries to the posterior part
2. Tonsillar branch of the facial artery
3. Ascending pharyngeal artery.

**FIG. 13.18** ■ Arterial supply of the tongue. FA, facial artery; EC, external carotid artery.

### N.B.

The deep lingual artery anastomoses with its fellow of the opposite side near the tip of the tongue. It is the only significant anastomoses across the midline of the tongue.

### Venous drainage AN 39.1

It is by the following veins:

1. **Deep lingual vein** is the *principal vein of the tongue* and is visible on the inferior surface of the tongue near the median plane through thin mucous membrane in life.
2. **Venae comitantes** accompanying the lingual artery. They are joined

by *dorsal lingual veins*.

3. **Venae comitantes** accompanying the hypoglossal nerve.

These veins unite at the posterior border of the hyoglossus to form the **lingual vein**, which drains into either common facial vein or internal jugular vein.

### **Lymphatic drainage AN 39.1**

The lymphatics emerging from the tongue are grouped into the following four sets ([Fig. 13.19](#)):

1. **Apical vessels** : They drain the tip and inferior surface of the tongue bilaterally into submental lymph nodes after piercing the mylohyoid muscle. Their efferents go to the submandibular nodes mainly, some cross the hyoid bone to reach the jugulo-omohyoid nodes.
2. **Marginal vessels** : They drain marginal portions of the anterior two-third of the tongue unilaterally into submandibular lymph nodes and then to the lower deep cervical lymph nodes, including jugulo-omohyoid.
3. **Central vessels** : They drain the central portion of the anterior two-third of the tongue (i.e., area within 0.5 inch on either side of midline). They pass vertically downwards in the midline of the tongue between the genioglossus muscles and then drain bilaterally into the deep cervical lymph nodes.
4. **Basal vessels** : They drain the root of the tongue and posterior one-third of the tongue bilaterally into upper deep cervical lymph nodes, including jugulodigastric.

**FIG. 13.19** ■ Lymphatic drainage of the tongue: ( **A** ) course and direction of apical, marginal, and basal lymph vessels; ( **B** ) course and direction of central lymph vessels. Figure in the inset shows area (*in red*) having bilateral lymphatic drainage.

## CLINICAL CORRELATION

**Prognosis of tongue cancer:** There is rich anastomosis across the midline between the lymphatics of the posterior one-third of the tongue; therefore, a cancer on one side readily metastasizes to ipsilateral as well as the contralateral lymph nodes. In contrast, there is little cross-communication of

lymphatics of the anterior two-third of the tongue where cancer, more than 0.5 inch (12 mm) away from the midline, does not metastasize to the contralateral lymph nodes till very late stage. For this reason, cancer in the posterior one-third of the tongue has poor prognosis.

**Nerve supply (Fig. 13.20 ) AN 39.1**

The nerves supplying the tongue are as follows:

*Motor supply:* All the muscles of tongue (intrinsic and extrinsic) are supplied by the hypoglossal nerve *except* palatoglossus which is supplied by cranial root of accessory via pharyngeal plexus.

*Sensory supply:* Anterior two-third of the tongue is supplied by:

- (a) Lingual nerve carrying general sensations
- (b) Chorda tympani nerve carrying special sensations of taste.

Posterior one-third of the tongue is supplied by:

- (a) Glossopharyngeal nerve, carrying both general and special sensations of taste
- (b) Posterior-most part (base of the tongue) is supplied by the internal laryngeal branch of the superior laryngeal carrying special sensations of taste

**FIG. 13.20** ■ Nerve supply of the tongue. Right half of the figure shows motor supply and left half shows sensory supply.

### N.B.

Nerves carrying taste sensations from the tongue are as follows (Fig. 13.21):

- *Chorda tympani* nerve (a branch of the facial nerve) from anterior two-thirds of the tongue
- *Glossopharyngeal* nerve from posterior one-third of the tongue
- *Internal laryngeal* nerve from superior laryngeal branch of the vagus nerve, from posterior-most part of the tongue.

**FIG. 13.21** ■ Nerves carrying taste sensations from the tongue.

### **CLINICAL CORRELATION**

**Referred pain of cancer tongue:** The patients with cancer tongue often complain of pain in ear, temporomandibular joint, temporal fossa, and/or lower teeth.

This is due to *referred pain*. It is important to note that pain is frequently referred from one branch of the mandibular nerve to the other. Carcinoma commonly involves anterior two-third of tongue. Thus, if the sensations carried from anterior two-third of the tongue by the lingual nerve are referred to auriculotemporal nerve, the patient feels pain in the ear, TMJ and temporal fossa. On the contrary, if the pain from lingual nerve is referred to the inferior alveolar nerve, the pain is felt in the lower teeth.

**Development of the tongue (Fig. 13.22 )**

The tongue develops around 4th week of IUL from the floor of the primitive pharynx in relation to 1st, 2nd, 3rd and 4th the pharyngeal arches.

**FIG. 13.22 ■** Development of the tongue: ( **A** ) appearance of four swellings in the floor of primitive pharynx; ( **B** ) formation of anterior two-third by the growth and fusion of two lingual swellings and posterior one-third by the growth and fusion of cranial part of the hypobranchial eminence.

## Development of mucous membrane of the tongue

The mucous membrane of the anterior two-third of tongue develops from the fusion of a **pair of lingual swellings** with the **tuberculum impar** . The lingual swellings appear as endodermal thickenings at the anterior ends of the 1st pharyngeal arches. The tuberculum impar appears as a median swelling just behind the lingual swellings between 1st and 2nd pharyngeal arches. The tuberculum impar soon disappears; thus, the oral part is mostly bilateral in origin.

The lingual swellings fuse in the midline forming a median sulcus. The mucous membrane of posterior one-third of the tongue develops from the cranial part of **hypobranchial eminence** . The hypobranchial eminence (*copula of His* ) appears as a median swelling due to thickening of endoderm connecting ventral ends of 2nd, 3rd, and 4th pharyngeal arches. It soon divides into two parts: a cranial part related to the 2nd and 3rd arches and a caudal part related to the 4th arch.

The 3rd arch endoderm grows forwards over the 2nd arch to fuse with the lingual swellings and tuberculum impar and gives rise to the mucous membrane of the posterior one-third of the tongue. The 3rd arch grows forwards in a V-shaped manner and fuses with the anterior two-third of the tongue. The line of fusion is indicated by **sulcus terminalis** .

The mucous membrane of the posterior-most part of the tongue is derived from the 4th pharyngeal pouch.

The foramen caecum represents the site of development of thyroglossal duct forming thyroid gland in the embryo.

## Development of muscles of the tongue

The muscles of tongue develop from **occipital myotomes** , which at first are closely related to developing hindbrain and later migrate anteroinferiorly around the pharynx and enter the tongue. The migrating myotomes carry with them their nerve supply – the 12th cranial nerve.

## Correlation of nerve supply of the tongue with its development

### Motor innervation

Muscles of the tongue are supplied by the hypoglossal nerve because they develop from occipital myotomes (occipital myotomes are formed by the fusion of precervical somites).

## Sensory innervation

1. **Anterior two-third** develops from the 1st pharyngeal arch. Since mucosa overlying this area has its origin from 1st and 2nd arches therefore, it is supplied by:
  - (a) *Lingual nerve* , the **post-trematic nerve** of the 1st arch
  - (b) *Chorda tympani nerve* , the **pre-trematic nerve** of the 1st arch.
2. **Posterior one-third** develops from the 3rd pharyngeal arch, hence the mucosa overlying this area is supplied by the **glossopharyngeal nerve** , the nerve of the 3rd arch.
3. **Posterior-most part** develops from the 4th laryngeal arch, hence mucosa overlying this area is supplied by the **internal laryngeal nerve** , the nerve of the 4th arch.

The correlation between nerve supply of the tongue with its development is also presented in [Table 13.6](#) .

 **TABLE 13.6**

### Correlation of nerve supply of the tongue with its development AN 39.1

Structures	Source of development	Nerve supply
<b>Muscles</b>	Occipital myotomes	Hypoglossal nerve
<b>Mucous membrane</b>		
(a) Anterior two-third of tongue	1st arch	<ul style="list-style-type: none"><li>• Lingual nerve (post-trematic nerve of 1st arch)</li><li>• Chorda tympani nerve (pre-trematic nerve of 1st arch)</li></ul>
(b) Posterior one-third of tongue	3rd arch	<ul style="list-style-type: none"><li>• Glossopharyngeal nerve (nerve of 3rd arch)</li></ul>

(c) Posterior-most part of tongue	4th arch	• Internal laryngeal nerve (nerve of 4th arch)
-----------------------------------	----------	--

### Golden Facts to Remember

• Hardest substance/structure in the body	Enamel of the tooth
• Most sensitive part of the tooth	Dentine
• Wisdom tooth	3rd molar
• Eye tooth	Upper canine
• First deciduous teeth to erupt	Mandibular central incisors (6 months)
• First permanent teeth to erupt	1st mandibular molars (6 years)
• Last permanent teeth to erupt	3rd molars (18–24 years)
• Last deciduous teeth to fall	Canines
• Most commonly impacted teeth	Mandibular 3rd molars
• Dental caries	Decay/cavitation of teeth
• Safety muscle of the tongue	Genioglossus
• Most common site of cancer tongue	Lateral margin of anterior two-third of tongue
• Principal lymph node of the tongue (lymph node of the tongue)	Jugulo-omohyoid

### CLINICAL CASE STUDY

A 67-year-old chronic tobacco chewer complained to his family physician about a sore on the side of his tongue for 6 months. He stated that he first thought that it was a simple sore and then he became worried because it now enlarged in size and looked different. On examination, the physician found an ulcerated and indurated (Latin, *indurare* = to harden) lesion on the lateral margin of the patient's tongue. The palpation of lymph nodes in the region of the neck revealed enlarged hard submandibular and lower deep cervical lymph nodes. He was referred to an ENT surgeon, who advised biopsy. The biopsy report revealed **squamous cell carcinoma of the tongue**.

## Questions

1. What is the commonest site of cancer of tongue?
2. What is lymphatic drainage of the side of anterior two-third of tongue?
3. In which location does cancer of tongue have poor prognosis and why?
4. Which lymph node is called lymph node of the tongue?
5. What is the most common cause of fatal haemorrhage in tongue cancer?

## Answers

1. Lateral margin of the anterior two-third of tongue.
2. Lymph from side of anterior two-third of tongue is drained into submandibular and lower deep cervical lymph nodes.
3. Posterior one-third of tongue because of bilateral spread of cancer.  
(Note that lymph from posterior one-third of tongue is drained bilaterally.)
4. Jugulo-omohyoid lymph node.
5. Erosion of deep lingual artery.

---

# Chapter 14: Pharynx and palate

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe pharynx under the following headings: (a) definition and location, (b) parts/subdivisions, (c) pharyngeal wall, (d) structures passing through the gaps in the pharyngeal wall, and (e) applied anatomy.
- Describe the components and functions of Waldeyer's lymphatic ring. **AN 36.2**
- Describe the clinical significance of Killian's dehiscence. **AN 36.5**
- Describe the palatine tonsil under the following headings: (a) location and external features, (b) relations, (c) blood supply, and (d) applied anatomy. **AN 36.1**
- Write short notes on: (a) Waldeyer's ring, (b) tonsillar bed, (c) soft palate, (d) auditory tube, and (e) arterial supply of tonsil.
- Describe the composition of soft palate. **AN 36.1**
- Give the anatomical/embryological basis of (a) adenoids, (b) pharyngeal diverticulum, (c) quinsy, (d) cleft palate, (e) gag reflex, and (f) effects of paralysis of soft palate.
- Describe the anatomical basis of tonsillitis, tonsillectomy, adenoids, and peritonsillar abscess. **AN 36.4**
- Describe the boundaries and clinical significance of piriform fossa. **AN 36.3**

## Pharynx

The pharynx is a funnel-shaped fibromuscular tube, extending from base of

the skull to the oesophagus (Fig. 14.1 ). It is lined throughout with mucous membrane. The pharynx acts as a common channel (Fig. 14.2 ) for both food (deglutition) and air (respiration).

**FIG. 14.1** ■ Sagittal section through the nose, mouth, pharynx, and larynx.

**FIG. 14.2 ■** Pathways for food (*red arrow*) and air (*green arrow*) through the pharynx.

## Measurements

<i>Length</i>	12–14 cm
<i>Width</i>	3.5 cm at its base
	1.5 cm at pharyngoesophageal junction.

## Location

It is situated behind the cavities of nose, mouth, and the larynx with which it communicates (Fig. 14.1 ).

## Boundaries and relations

<i>Superior</i>	Base of skull including the posterior part of the body of sphenoid and basilar part of occipital bone in front of pharyngeal tubercle.
<i>Inferior</i>	Continuous with the oesophagus at the level of lower border of cricoid cartilage anteriorly and lower border of C6 vertebra posteriorly.
<i>Posterior</i>	Prevertebral fascia in front of cervical spine. The pharynx is separated from prevertebral fascia only by a layer of loose areolar tissue, which allows the pharynx to slide freely on this fascia during swallowing.
<i>Anterior</i>	Opens into nasal cavities, mouth, and larynx.
<i>Lateral</i>	Neurovascular bundle of neck and styloid process with its attached muscles and ligaments.

### Subdivisions (Figs 14.2 –14.4 )

The pharynx is divided into three parts. From above downwards, these are as follows:

1. *Nasopharynx* , lying behind the nose
2. *Oropharynx* , lying behind the oral cavity
3. *Laryngopharynx* , lying behind the larynx.

**FIG. 14.3 ■** Subdivisions of the pharynx.

**FIG. 14.4 ■** Pharynx opened from behind showing features in the anterior walls of the nasopharynx, oropharynx, and laryngopharynx.

### **Nasopharynx**

The nasopharynx lies behind the nasal cavities and above the soft palate.

### **Boundaries**

*Roof:* It is formed by inferior surface of:

- (a) Body of sphenoid
- (b) Basisphenoid
- (c) Basiocciput (basilar part of the occipital bone)

*Floor:* It is formed by:

- (a) Soft palate (sloping upper surface)
- (b) Pharyngeal isthmus, an opening in the floor between the free edges of soft palate and posterior pharyngeal wall

*Anterior wall:* It is formed by posterior nasal apertures separated by the posterior edge of nasal septum.

*Posterior wall:* It forms continuous sloping surface with roof. It is supported by anterior arch of C1 vertebra.

*Lateral wall:* Medial pterygoid plate of sphenoid.

## Features

The features seen in the nasopharynx are as follows:

(a) **Nasopharyngeal (pharyngeal) tonsil** : It is a collection of lymphoid tissue beneath the mucous membrane behind the nasal cavity at the junction of the roof and posterior wall of the nasopharynx.

- The **nasopharyngeal bursa** (*pouch of Luschka*) is a recess in the midline of nasopharynx which is produced by the remnants of notochord. This bursa develops because of adhesion of notochord to the dorsal wall of the pharyngeal part of the foregut.

- Sometimes a small dimple is seen in the mucous membrane above the pharyngeal tonsil. It represents the remains of **Rathke's pouch** . A *craniopharyngioma* may arise from it.

(b) **Orifice of the pharyngotympanic tube or auditory tube (eustachian tube)** : This lies on the lateral wall at the level of the inferior nasal concha and 1.25 cm behind it.

- The upper and posterior margins of this opening are bounded by a tubal elevation, which is produced by the collection of lymphoid tissue called **tubal tonsil** . Two mucous folds extend from this elevation:

- (i) *Salpingopharyngeal fold* extends vertically downwards and fades on the side wall of the pharynx. It contains salpingopharyngeus muscle.
- (ii) *Salpingopalatine fold* extends downwards and forwards to

the soft palate. It contains the levator palatini muscle.

(c) **Pharyngeal recess:** It is a deep depression behind the tubal elevation; it is called **pharyngeal recess (fossa of Rosenmüller)** .

### **N.B.**

Structurally and functionally, nasopharynx resembles the nose. It is respiratory in function and lined by pseudostratified ciliated columnar epithelium. Its walls are rigid and noncollapsible to keep the air passage patent.

### **CLINICAL CORRELATION AN 36.4**

**Adenoids:** The nasopharyngeal tonsils are prominent in children up to the 6 years of age, then gradually undergo atrophy till puberty and almost completely disappear by the age of 20.

The nasopharyngeal tonsils when enlarged due to infection are known as *adenoids* , which block the posterior nares making ‘mouth breathing obligatory’.

The affected children present the following clinical features:

- Nasal obstruction
- Nasal discharge
- Mouth breathing with protrusion of tongue
- Toneless voice (due to absence of nasal tone)
- Small nose
- Epistaxis (i.e., nose bleeding).

The infection from pharynx can easily pass into middle ear through pharyngotympanic tube.

### **Nasopharyngeal isthmus and Passavant's ridge**

Some fibres of the palatopharyngeus muscle (arising from palatine aponeurosis) sweep horizontally backwards and join upper fibres of the superior constrictor muscle to form a **U-shaped muscle loop** in posterior pharyngeal wall underneath the mucosa, which is pulled forward during swallowing to form the **Passavant's ridge** . During swallowing, the pharyngeal isthmus (opening between the free edges of soft palate and posterior wall) is closed by the elevation of the soft palate and pulling forward of posterior pharyngeal wall (Passavant's ridge). This U-shaped muscle loop

thus acts as a palatopharyngeal sphincter.

## **Oropharynx (Figs 14.1 –14.3 )**

It lies behind the oral cavity and extends from lower surface of the soft palate above to upper border of epiglottis below.

### **Boundaries**

*Roof:* It is formed by:

- (a) Soft palate (undersurface)
- (b) Pharyngeal isthmus through which it communicates with the nasopharynx

*Floor:* It is formed by:

- (a) Posterior one-third of the tongue
- (b) Interval between the tongue and epiglottis

*Anterior wall:* It is incomplete and formed by:

- (a) Oropharyngeal isthmus (through which it opens into the oral cavity)
- (b) Pharyngeal part of the tongue

*Posterior wall:* It is formed by body of C2 vertebra and upper part of the body of C3 vertebra.

*Lateral wall:* On each side, it is supported by pterygomandibular raphe, mandible, tongue, and hyoid bone.

The oropharynx provides common path for the food and air.

### **Features**

The features seen in the oropharynx are as follows:

- (a) **Lateral wall presents** *palatine tonsils*, one on either side. It is located in a triangular fossa (tonsillar fossa) bounded anteriorly by palatoglossal arch and posteriorly by palatopharyngeal arch.
  - The palatoglossal arch runs downwards and forwards from palate to the lateral margin of the tongue. The palatopharyngeal arch runs downwards and backwards to the pharyngeal wall where it fades out (for details of palatine tonsil, see page 203).
- (b) **Anterior wall presents:**
  - (i) *Lingual tonsil* , formed by numerous nodules of lymphoid tissue underneath the mucous lining of the pharyngeal part of the

dorsum of the tongue.

(ii) *Upper free end of epiglottis* , behind the tongue.

(iii) *Median and lateral glossoepiglottic folds* , connecting the anterior surface and edges of the epiglottis, respectively to the tongue.

(iv) *Epiglottic valleculae* are shallow fossae between median and lateral glossoepiglottic folds.

### **Oropharyngeal isthmus (Fig. 14.5 )**

It is an arched opening between two palatoglossal folds through which the oral cavity communicates with the oropharynx. Its boundaries are as follows:

<i>Above</i>	Soft palate
<i>Below</i>	Dorsal surface of the posterior one-third of the tongue
<i>Lateral</i>	Palatoglossal fold/arch on either side containing palatoglossus muscle

**FIG. 14.5 ■** Boundaries of the oropharyngeal isthmus.

The oropharyngeal isthmus is closed during deglutition to prevent regurgitation of food from pharynx to the mouth.

## CLINICAL CORRELATION

**Choking and belching:** Because the pathways for food and air cross each other in the oropharynx, the food sometimes may enter into the respiratory tract and cause choking. Similarly, the air often enters the digestive tract producing gas in the stomach, which results in eructation (*belching*).

## Laryngopharynx

The laryngopharynx lies behind the laryngeal inlet and posterior wall of the larynx. It lies behind the larynx and extends from upper border of the epiglottis to the lower border of cricoid cartilage anteriorly and lower border of C6 vertebra posteriorly. It communicates anteriorly with the laryngeal cavity through **laryngeal inlet** and inferiorly with the oesophagus at the pharyngoesophageal junction (the narrowest part of the GIT except appendix).

## Boundaries

*Anterior wall:* It is formed by:

- (a) Laryngeal inlet
- (b) Posterior surface of the larynx

*Posterior wall:* It is supported by the bodies of C3, C4, C5, and C6 vertebrae.

*Lateral wall:* It is supported by thyroid cartilage and thyrohyoid membrane.

## Features

The features seen in the laryngopharynx are as follows:

- (a) **Anterior wall** presents laryngeal inlet, and below the inlet, it is supported by cricoid and arytenoid cartilages.
- (b) **Lateral wall** presents piriform fossa one on each side of laryngeal inlet.

## Piriform fossa AN 36.3

It is a deep recess broad above and narrow below in the anterior part of lateral

wall of the laryngopharynx, on each side of the laryngeal inlet. These recesses are produced because of bulging of larynx into laryngopharynx.

### Boundaries (Fig. 14.6 )

<i>Medial</i>	Aryepiglottic fold and quadrangular membrane of larynx
<i>Lateral</i>	Mucous membrane covering the medial surface of the lamina of thyroid cartilage and thyrohyoid membrane
	The <i>internal laryngeal nerve</i> and <i>superior laryngeal vessels</i> pierce the thyrohyoid membrane and traverse underneath the mucous membrane of the floor of the fossa to reach the medial wall
<i>Above</i>	Piriform fossa is separated from epiglottic vallecula by lateral glossoepiglottic fold.

**FIG. 14.6** ■ Schematic coronal section through larynx

showing location and boundaries of the piriform fossa.

Also see [Chapter 15 Figs 15.10 and 15.11](#) .

### **N.B.**

- The piriform fossa is deep in ruminating animals in which it acts as *lateral food channel* to convey the bolus of food during deglutition by the side of closed laryngeal inlet.
- It is sometimes, artificially deepened by smugglers using lead balls to hide precious materials such as diamonds. For this reason, the piriform fossa is also called *smuggler's fossa* .

### **CLINICAL CORRELATION**

#### **Clinical significance of piriform fossa:**

These are as follows:

- (a) The piriform fossae are dangerous sites for perforation by an endoscope.
- (b) A malignant tumour of the laryngopharynx (hypopharynx) may grow in the space provided by the piriform fossa without producing symptoms until the patient presents with metastatic lymphadenopathy.
- (c) The ingested foreign bodies (e.g., fish bones and safety pins) are sometimes lodged into the piriform fossa. If care is not taken, removal of foreign bodies may damage the internal laryngeal nerve leading to anaesthesia in the supraglottic part of the larynx and subsequent loss of *protective cough reflex* .

### **Pharyngeal wall (Fig. 14.7 )**

The wall of the pharynx consists of four layers; from within outwards, these are as follows:

1. Mucous membrane/mucous coat
2. Pharyngobasilar fascia (pharyngeal aponeurosis)
3. Muscular coat (pharyngeal muscles)
4. Buccopharyngeal fascia (loose areolar sheath).

**FIG. 14.7 ■** Structure of the pharyngeal wall.

### **Mucous membrane/mucous coat**

The mucous membrane lining the pharynx contains a considerable amount of elastic tissue and is continuous with the mucous lining of eustachian tubes, nasal cavities, mouth, larynx, and oesophagus. It is lined by nonkeratinized stratified squamous epithelium except in the region of the nasopharynx, where it is lined by ciliated columnar epithelium (respiratory epithelium).

### **N.B.**

There are many subendothelial collections of lymphoid tissue around the commencement of food and air passages, into which epithelium tends to invaginate in the form of narrow clefts (crypts).

These collections of lymphoid tissue form pharyngeal and tubal tonsils in the nasopharynx and palatine, and lingual tonsils in the oropharynx.

## Pharyngobasilar fascia

It is a fibrous thickening of the submucosa. It lines the muscular coat and is thick near the base of the skull but thin and indistinct inferiorly. The pharyngobasilar fascia is thickest: In the upper part, where it fills the gap between the upper border of superior constrictor and the base of the skull.

## Muscular coat

The muscular coat consists of the following two layers of striated muscles:

- (a) The **outer layer** comprises three pairs of circular muscles called *constrictors*.
- (b) The **inner layer** comprises three pairs of longitudinal muscles.

The pharyngeal muscles are described in detail under the heading ‘Muscles of the Pharynx’.

## Buccopharyngeal fascia

It is an inconspicuous fascia, which covers the outer surface of constrictor muscles. In the upper part, it is also prolonged forwards to cover the buccinator muscles, hence the name *buccopharyngeal fascia*. Above the upper border of the superior constrictor, it blends with the pharyngobasilar fascia.

### CLINICAL CORRELATION AN 36.2

**Waldeyer's ring:** The aggregations of lymphoid tissue underneath the epithelial lining of pharyngeal wall called tonsils, surround the commencement of air and food passages. These aggregations together constitute an interrupted circle called *Waldeyer's ring*, which forms special feature of the interior of the pharynx.

#### Components

The Waldeyer's ring is formed by ([Fig. 14.8](#)):

- Pharyngeal tonsil (nasopharyngeal tonsil), posterosuperiorly
- Lingual tonsil, anteriorly
- Tubal and palatine tonsils, laterally.

#### Functions

It is thought that Waldeyer's ring prevents invasion of microorganisms from

entering the air and food passages and this helps in the defence mechanism of the respiratory and alimentary systems.

**FIG. 14.8** ■ Waldeyer's ring (an interrupted 'circle of tonsils' at the upper end of the respiratory and alimentary tracts).

## Muscles of the pharynx

### Constrictor muscles (Figs 14.9 and 14.10 )

The *three constrictor muscles of the pharynx* (superior, middle, and inferior) are arranged like a flowerpot without base, placed one above the other and open in front for communication with the nasal, oral, and laryngeal cavities. Thus, inferior constrictor overlaps the middle, which in turn overlaps the superior constrictor (Fig. 14.9 , inset).

**FIG. 14.9** ■ Overlapping arrangement of the constrictor muscles of the pharynx. The figure in the inset shows flowerpot arrangement of the constrictors. SC, superior constrictor; MC, middle constrictor, IC, inferior constrictor.

The **constrictor muscles** form bulk of the muscular coat of the pharyngeal wall. They arise in front from the margins of posterior openings of the nasal, oral, and laryngeal cavities. The fibres pass backwards, in a fan-shaped manner into the lateral and posterior walls of the pharynx to be inserted into the median fibrous raphe on the posterior aspect of the pharynx, extending from the base of the skull (pharyngeal tubercle of occipital bone) to the oesophagus. The origin and insertion of constrictions of the pharynx are shown in [Figure 14.10](#) .

**FIG. 14.10 ■** Origin and insertion of constrictors of the pharynx.

The origin, insertion, nerve supply, and actions of the constrictor muscles are presented in [Table 14.1](#).

### **TABLE 14.1**

#### **Origin, insertion, nerve supply, and actions of the constrictor muscles of the pharynx**

<b>Muscle</b>	<b>Origin</b>	<b>Insertion</b>	<b>Nerve supply</b>
<b><i>Superior constrictor</i></b> (quadrilateral in shape)	(a) Pterygoid hamulus (b) Pterygomandibular raphe (c) Medial surface of the mandible at the upper end of mylohyoid line (d) Side of the posterior part of the tongue	(a) Pharyngeal tubercle on the base of skull (b) Median fibrous raphe	Pharyngeal branch of the vagus nerve carrying fibres of cranial root of the accessory nerve
<b><i>Middle constrictor</i></b> (fan shaped)	(a) Lower part of the stylohyoid ligament (b) Lesser cornu of hyoid (c) Upper border of greater cornu of hyoid	Median fibrous raphe	Pharyngeal branch of the vagus nerve carrying fibres of cranial root of the accessory nerve
<b><i>Inferior constrictor</i></b> (a) Thyropharyngeus	(a) Oblique line on lamina of the thyroid cartilage (b) Tendinous band between the thyroid (inferior) tubercle and cricoid cartilage	Median fibrous raphe	(a) Pharyngeal plexus (b) External laryngeal nerve

(b) Cricopharyngeus	Cricoid cartilage	Median fibrous raphe	Recurrent laryngeal nerve
------------------------	-------------------	----------------------------	---------------------------------

### CLINICAL CORRELATION AN 36.5

**Pharyngeal pouch (also called Zenker's diverticulum):** Inferior constrictor muscle has two parts: *thyropharyngeus* made up of oblique fibres and *cricopharyngeus* made up of transverse fibres.

The potential gap posteriorly between the thyropharyngeus and cricopharyngeus is called **pharyngeal dimple** or **Killian's dehiscence** (Fig. 14.11). The mucosa and submucosa of the pharynx may bulge through this weak area to form a pharyngeal pouch or diverticulum (Fig. 14.12 A and B).

The formation of pharyngeal pouch in the region of Killian's dehiscence is attributed to the *neuromuscular incoordination* in this region, which may be because the two parts of the inferior constrictor have different nerve supply. The propulsive thyropharyngeus is supplied by the pharyngeal plexus and the sphincteric cricopharyngeus is supplied by the recurrent laryngeal nerve. If the cricopharyngeus fails to relax when the thyropharyngeus contracts, the bolus of food is pushed backwards and tends to produce a diverticulum.

**FIG. 14.11** ■ Killian's dehiscence.

**FIG. 14.12 ■** Pharyngeal pouch (diverticulum): ( **A** ) schematic diagram; ( **B** ) as seen in barium swallow.

(Source: *B, Last's Anatomy: Regional and Applied*, 12th Edition, Chummy S Sinnatamby. Chapter 6: Head and Neck and Spine, Fig. 6.38, page 385, Copyright 2011, Churchill Livingstone, Elsevier.)

### Gaps in the pharyngeal wall

The four gaps exist on either side in the pharyngeal wall in relation to constrictor muscles. The gaps and structures passing through these gaps (Fig. 14.13 ) are presented in Table 14.2 .

**FIG. 14.13** ■ Structures passing through the gaps in the pharyngeal wall.

## TABLE 14.2

### Gaps in the pharyngeal wall and structures passing through them

Gap	Structures passing through them
Between base of skull and upper concave border of superior constrictor ( <b>sinus of Morgagni</b> )	<ul style="list-style-type: none"> <li>• Auditory tube</li> <li>• Levator palatini muscle</li> <li>• Ascending palatine</li> </ul>

	artery • Palatine branch of the ascending pharyngeal artery
Between superior and middle constrictors	• Stylopharyngeus muscle • Glossopharyngeal nerve
Between middle and inferior constrictors	• Internal laryngeal nerve • Superior laryngeal vessels
Between lower border of inferior constrictor and oesophagus (in the tracheoesophageal groove)	• Recurrent laryngeal nerve • Inferior laryngeal vessels

### **Longitudinal muscles (Fig. 14.14 )**

These muscles run longitudinally from above downwards to form the longitudinal muscle coat (Table 14.3 ). The origin, insertion, and nerve supply of the longitudinal muscles are presented in Table 14.3 .

**FIG. 14.14** ■ Origin and insertion of the longitudinal muscles of the pharynx. SC, superior constrictor; MC, middle constrictor; IC, inferior constrictor.

### **TABLE 14.3**

#### **Origin, insertion, and nerve supply of the longitudinal muscles of the pharynx**

<b>Muscle</b>	<b>Origin</b>	<b>Insertion</b>	<b>Nerve supply</b>
<b><i>Stylopharyngeus</i></b>	Medial surface of the base of styloid process	Posterior border of the lamina of thyroid cartilage	Glossopharyngeal (9th) nerve
<b><i>Palatopharyngeus</i></b>	By two fasciculi (anterior and posterior) from the upper surface of the palatine aponeurosis	Posterior border of the lamina of thyroid cartilage	Cranial root of 11th cranial nerve by pharyngeal plexus
<b><i>Salpingopharyngeus</i></b>	Lower part of the cartilage of the auditory tube	Posterior border of the lamina of thyroid cartilage	Cranial root of 11th cranial nerve by pharyngeal plexus

### **Actions of the longitudinal muscles**

They elevate the larynx and shorten the pharynx during swallowing. At the same time, palatopharyngeal sphincter formed by some fibres of the palatopharyngeus muscle closes the nasopharyngeal isthmus.

### **Nerve supply of the pharynx**

**Motor:** All the pharyngeal muscles are supplied by cranial root of accessory nerve (via pharyngeal branch of vagus and pharyngeal plexus), except the stylopharyngeus which is supplied by the glossopharyngeal nerve.

**Sensory:**

1. *Nasopharynx* , by pharyngeal branch of the pterygopalatine ganglion carrying fibres from maxillary division of the trigeminal nerve
2. *Oropharynx* , by glossopharyngeal nerve
3. *Laryngopharynx* , by the internal laryngeal nerve.

### **Pharyngeal plexus of the nerves**

It lies on the posterolateral aspect of the pharynx over the middle constrictor

underneath the buccopharyngeal fascia.

It is formed by:

1. Pharyngeal branch of the vagus nerve carrying fibres from cranial part of the accessory nerve
2. Pharyngeal branch of the glossopharyngeal nerve
3. Pharyngeal branch from superior cervical sympathetic ganglion.

### **Arterial supply of the pharynx**

The branches of the following arteries supply the pharynx:

1. Ascending pharyngeal artery (from external carotid artery)
2. Ascending palatine and tonsillar artery (from facial artery)
3. Greater palatine and pharyngeal artery (from maxillary artery)
4. Lingual artery (from external carotid artery).

### **Venous drainage of the pharynx**

The venous blood from pharynx is largely drained into **pharyngeal venous plexus**, which, like the pharyngeal nerve plexus, is situated on the posterolateral aspect of the pharynx over the middle constrictor. It drains into the internal jugular vein.

### **Lymphatic drainage of the pharynx**

The lymph from pharynx is drained into the upper and lower deep cervical lymph nodes directly and through retropharyngeal lymph nodes.

### **Deglutition (swallowing)**

The deglutition is a process or act by which the food is transferred from the mouth to the stomach ([Fig 14.15](#) ). It consists of the following three successive stages/phases:

1. First stage – voluntary
2. Second stage – involuntary
3. Third stage – involuntary.

**FIG. 14.15 ■** Stages of swallowing. A. First stage, B. Second stage, C, third stage.

### **First stage (voluntary)**

*In this stage, bolus of food passes from mouth to the oropharynx . Food is masticated, mixed with saliva and bolus is made. The bolus is put on the dorsum of tongue. Now the anterior part of tongue is raised and pressed against the hard palate. This movement takes place from anterior to posterior side and pushes the bolus of food in the posterior part of the oral cavity. Now the hyoid bone moves upwards and forward by suprahyoid muscles, and food is pushed from oral cavity to the oropharynx through oropharyngeal isthmus.*

### **Second stage (involuntary)**

*In this stage bolus of food moves from oropharynx to the oesophagus . This stage is very rapid. The nasopharyngeal isthmus is closed by the elevation of the soft palate and contraction of Passavant's ridge to prevent entry of food into the nasopharynx. The laryngeal inlet is closed by approximation of the aryepiglottic folds to prevent entry of food into the larynx. Now the pharynx and larynx are elevated behind the hyoid bone by the longitudinal muscles of the pharynx, and the bolus of food is pushed down over the posterior surface of the epiglottis by gravity and contraction of superior and middle constrictors. Thus, food passes from oropharynx to the laryngopharynx. The upward movement of larynx enlarges the opening of oesophagus which is normally a slit.*

*Now the pharyngeal wall contracts and peristaltic wave is initiated in the pharynx. Cricopharyngeus sphincter is relaxed and food passes from pharynx to oesophagus. This is followed by rapid downward displacement of the larynx and pharynx (by infrahyoid muscles), which reopens the laryngeal orifice.*

### **Third stage (involuntary)**

*In this stage, food passes from oesophagus to the stomach . The pharyngeal peristaltic wave continues into the oesophagus which travels from above downwards. As they reaches the cardiac sphincter, this sphincter relaxes and food passes from oesophagus to the stomach.*

## **Pharyngeal spaces AN 35.10**

These are potential spaces in relation to pharynx, namely:

1. **Retropharyngeal space** (Fig 14.16 ): It is situated behind the pharynx and extends from the base of the skull above to the bifurcation of trachea below. For details, see also page 75 [Chapter 4](#) .
2. **Parapharyngeal space** (Fig. 14.16 ): It is an inverted pyramid-shaped space situated on the side of the pharynx. It extends from base of skull above to the hyoid bone below. It contains carotid artery, internal jugular vein, last four cranial nerves, and cervical sympathetic chain. It is bounded by pharyngeal wall medially and mandible laterally.

**FIG. 14.16** ■ Parapharyngeal or lateral pharyngeal space.

The parapharyngeal space is potential site of tumour and abscess.

## Palatine tonsils AN 36.1

There are two palatine tonsils (commonly called *tonsils* ). Each tonsil is an almond-shaped mass of lymphoid tissue situated on either side in the triangular fossa (tonsillar fossa) of the lateral wall of the oropharynx between anterior and posterior pillars of fauces. The anterior pillar is formed by palatoglossal arch and posterior pillar is formed by palatopharyngeal arch (Fig. 14.17 ).

**FIG. 14.17** ■ Horizontal section through tonsillar fossa showing medial and lateral surfaces of the tonsil and tonsillar bed.

### N.B.

The actual size of tonsil is much bigger than what it appears on oropharyngeal examination because parts of tonsil extend upwards into the soft palate, downwards into the base of the tongue and anteriorly underneath

the palatoglossal arch.

### Boundaries of the tonsillar fossa/sinus

<i>Anterior</i>	Palatoglossal arch containing palatoglossus muscle
<i>Posterior</i>	Palatopharyngeal arch containing palatopharyngeus muscle
<i>Apex</i>	Soft palate, where both arches meet
<i>Base</i>	Dorsal surface of the posterior one-third of the tongue
<i>Lateral wall (or tonsillar bed)</i>	Superior constrictor muscle (mainly)

### Tonsillar bed (Fig. 14.17 )

It is formed from within outwards by:

- (a) Pharyngobasilar fascia
- (b) Superior constrictor muscle
- (c) Buccopharyngeal fascia.

### External features

The tonsil presents the following external features:

1. **Medial surface:** It is free and bulges into the oropharynx. It is lined by nonkeratinized stratified squamous epithelium, which dips into the substance of tonsil forming crypts. The number of tonsillar crypts varies from 12 to 15 and their openings can be seen on the medial surface. One of the crypts situated near the upper part of the tonsil is very large and deep. It is called **crypta magna** or **intratonsillar cleft** and represents the remnant of the second pharyngeal pouch. The crypts may be filled with cheesy material consisting of epithelial cells, bacteria, and food debris.
2. **Lateral surface ( Figs 14.17 and 14.18 ):** It is covered by a well-defined fibrous tissue, which forms the tonsillar hemicapsule. Between the capsule and the bed of tonsil is the loose areolar tissue (peritonsillar space), which makes it easy to dissect the tonsil in this

plane during **tonsillectomy** . It is also the site of collection of pus in **peritonsillar abscess** .

◦The superior constrictor separates this surface from the following structures ([Fig. 14.18](#) ):

- (a) Facial artery and two of its branches, the ascending palatine and tonsillar arteries
- (b) Styloglossus muscle and glossopharyngeal nerve
- (c) Styloid process (when elongated)
- (d) Angle of mandible and medial pterygoid muscle
- (e) Submandibular salivary gland.

◦The internal carotid artery is approximately 2.5 cm posterolateral to the tonsil.

3. **Anterior border:** It passes underneath the palatoglossal arch.
4. **Posterior border:** It passes underneath the palatopharyngeal arch.
5. **Upper pole:** It extends up into the soft palate. Its medial surface is covered by a semilunar fold extending between the anterior and posterior pillars enclosing a potential space called *supratonsillar fossa*.
6. **Lower pole:** It is attached to the tongue by a band of fibrous tissue called *suspensory ligament of the tonsil*.

**FIG. 14.18 ■** Horizontal section through right palatine tonsil showing structures deep to its lateral surface.

### **N.B.**

A triangular fold of mucous membrane extends from anterior pillar to the anteroinferior part of the tonsil. It encloses a potential space called **anterior tonsillar space**.

The tonsil is separated from the tongue by a sulcus called **tonsillolingual sulcus**.

*Surface anatomy:* An oval area 1.25 cm above and in front of the angle of the mandible, marked in the parotid region of face indicates the location of tonsil on the surface.

### **Arterial supply of the tonsil (Fig. 14.19 )**

The following arteries supply the tonsil:

1. Tonsillar branch of facial artery (it is the principal artery and enters the lower pole of the tonsil by piercing the superior constrictor)
2. Tonsillar branches of dorsal linguae artery
3. Ascending palatine, a branch of facial artery

4. Ascending pharyngeal, a branch of external carotid artery
5. Greater palatine (descending palatine), a branch of maxillary artery.

**FIG. 14.19** ■ Arteries supplying the tonsil.

### **Venous drainage of the tonsil**

The veins from tonsil drain into paratonsillar vein. The paratonsillar vein descends from the soft palate across the lateral aspect of the tonsillar capsule and pierces the superior constrictor to drain into **pharyngeal venous plexus** .

### **Lymphatic drainage of the tonsil**

The lymphatics of tonsil pierce the superior constrictor and drain into the

upper deep cervical lymph nodes, particularly the jugulodigastric lymph node. It is often called **tonsillar lymph node** because it is primarily enlarged in infection of the tonsil (tonsillitis). The tonsillar lymph node is located below the angle of the mandible.

### Nerve supply of the tonsil

Palatine tonsil is supplied by the glossopharyngeal nerve and lesser palatine branches of the sphenopalatine ganglion.

### CLINICAL CORRELATION AN 36.4

- **Acute tonsillitis:** The tonsils are the frequent sites of acute infection, especially in school-going children. It may affect adults also. This condition is called *acute tonsillitis*. It is mostly seen in viral infection. It is rare in infants and persons older than 50 years.
- **Acute follicular tonsillitis:** In this condition, the infection spreads into crypts, which become filled with purulent material presenting at the openings of crypts as *yellowish spots*.
- **Peritonsillar abscess Quinsy:** It is accumulation of pus behind tonsil in the peritonsillar space due to infection. Clinically, it presents as throat pain, difficulty in opening mouth. It usually occurs because of improperly treated episodes of acute tonsillitis.
  - ◊ If not treated, it may lead to airway obstruction and aspiration pneumonia.
  - ◊ **Tonsillectomy:** It is the surgical removal of tonsils if they are frequently infected and causes swelling with difficulty in breathing during sleep. During removal, utmost care should be taken to avoid damage of hemicapsule of tonsil, inadvertently.
- **Bleeding from tonsillar fossa after tonsillectomy:** It most commonly occurs because of damage of *paratonsillar vein*. The blood clots should be removed in order to check bleeding. If not removed, they interfere with the retraction of the vessel walls by preventing the contraction of the surrounding muscles. The postoperative oedema of tonsillar bed after tonsillectomy can affect the glossopharyngeal nerve leading to loss of sensation in the posterior one-third of the tongue.

### Microscopic features (Fig. 14.20 )

Microscopically, the tonsil presents the following features:

1. Its oral surface is lined by stratified squamous nonkeratinized epithelium, which dips many times into underlying tonsillar tissues to form crypts.
2. Presence of lymphatic nodules with germinal centres on the sides of the crypts into lamina propria.
3. Presence of mucous glands in the deeper plane, which open into bases of crypts.

**FIG. 14.20 ■** Histological structure of the palatine tonsil. (Source: Fig. 14.6 , page 147, *Selective Anatomy: Prep Manual for Undergraduates* , Vol. I, Vishram Singh, Copyright Elsevier 2014, All rights reserved.)

### Development of the tonsil

The tonsil develops in the region of 2nd pharyngeal pouch. The cells of endodermal lining of pouch proliferate and grow out as solid columns/buds into the surrounding mesenchyme. The central portions of these cell columns are canalized and form tonsillar clefts. The lymphoid cells from the surrounding mesenchyme accumulate around the crypts and differentiate into lymphoid follicles. The remnant of 2nd pharyngeal pouch is seen as supratonsillar/infratonsillar cleft at the upper pole of the tonsil.

### Pharyngotympanic tube (SYN. Eustachian tube/auditory tube)

It is a mucous-lined osseocartilaginous channel, which connects the nasopharynx with the tympanic cavity (Fig. 14.21 ). It maintains the equilibrium of air pressure on either side of the tympanic membrane for its proper vibration.

**FIG. 14.21 ■** Bony and cartilaginous parts, isthmus, tympanic and pharyngeal ends of the pharyngotympanic tube.

In an adult, it is approximately 36 mm long and runs downwards, forwards, and medially from its tympanic end.

### **Parts (Fig. 14.9 )**

The pharyngotympanic tube is divided into two parts, namely:

1. **Osseous or bony part:** It is posterolateral part and forms one-third (12 mm) of the total length of the tube. It lies between the tympanic and petrous parts of the temporal bone and opens into the middle ear cavity.
2. **Cartilaginous part:** It is anteromedial part and forms two-third (24 mm) of the tube.

The two parts meet at isthmus, which is the narrowest part of the tube. The cartilaginous part is made of a single piece of elastic fibrocartilage, which is

folded upon itself in such a way that it forms the whole of the medial wall, roof, and a part of the lateral wall. The rest of the lateral wall is filled by the fibrous membrane.

The cartilaginous part lies in the groove between the petrous part of the temporal bone and the posterior border of the greater wing of the sphenoid bone.

**Ends of the tube**

The **tympanic end** of the tube is small and bony. It is situated in the anterior wall of the middle ear, a little above its floor.

The **pharyngeal end** is relatively large and slit-like (vertically). It is situated in the lateral wall of the pharynx, approximately 1.25 cm behind the posterior end of inferior nasal concha. The pharyngeal orifice is the widest part of the tube.

**Lining of the tube**

The tube is lined by pseudostratified ciliated columnar epithelium with interspersed goblet cells. The cilia beat in the direction of nasopharynx and thus help to drain the secretions and fluid from the middle ear into the nasopharynx.

**Pharyngotympanic tubes of an infant and an adult**

The features of the tube differ in infants and adults. These are enumerated in [Table 14.4](#) .

 **TABLE 14.4**

**Differences between eustachian tube of an infant and an adult**

	Infant	Adult
<b>Length</b>	18 mm	36 mm
<b>Direction</b>	More or less horizontal (makes an angle of 10 degrees with the horizontal plane)	Oblique, directed downwards, forwards, and medially (makes an angle of 45 degrees with the horizontal plane)
<b>Angulation of isthmus</b>	No angulation	Angulation present

## CLINICAL CORRELATION

Because the eustachian tube is shorter, wider, and more horizontal in infants, infection from nasopharynx can easily reach the middle ear; for this reason, **middle ear infections are more common in infants and young children than in adults**.

## Functions

The following are the functions of the pharyngotympanic tube:

1. Maintains equilibrium of air pressure on either side of tympanic membrane. At rest, the tube remains closed but during swallowing, yawning, and sneezing, it reflexly opens.
2. Protection of middle ear by preventing the transmission of high sound pressure from nasopharynx to middle ear because normally the tube remains closed.
3. Clearance of middle ear secretions by active opening and closing of the tube. The cilia of mucous lining of the tube beat in the direction of nasopharynx and drain the secretion of the middle ear into the nasopharynx.

## N.B.

An individual swallows once every minute when awake and once every 5 min when asleep.

## CLINICAL CORRELATION

**Effects of blockage of pharyngotympanic tube:** The pharyngotympanic tube equalizes the pressure in the middle ear with the atmospheric pressure to permit free movement of the tympanic membrane. If the tube is blocked because of inflammation of tubal tonsil, residual air in the middle ear is absorbed into the blood vessels of its mucous membrane, causing a fall of pressure in it and consequent **retraction of tympanic membrane (RTM)**. This causes disturbance of hearing and severe earache because of RTM. The persistently reduced air pressure within the middle ear is corrected by periodic introduction of air by eustachian catheter.

## Palate

The term *palate* refers to the roof of the mouth (Latin, *palate* = roof of the mouth). It forms a partition between the nasal and oral cavities.

The palate consists of two parts:

1. **Hard palate** , which forms the anterior four-fifth of the palate
2. **Soft palate** , which forms the posterior one-fifth of the palate.

## Hard palate

The hard palate is a partition between nasal and oral cavities. Its anterior two-third is formed by the palatine processes of the maxillae and posterior one-third by the horizontal plates of the palatine bones (Fig. 14.22 ).

**FIG. 14.22** ■ Oral aspect of the hard palate.

The superior and inferior surfaces of the hard palate form the floor of the nasal cavity and the roof of the oral cavity, respectively.

**Anterolaterally**, the hard palate becomes continuous with the alveolar arches and gums.

The *posterior margin* of the hard palate is free and provides attachment to the soft palate.

## Features on the inferior surface of hard palate

The **inferior surface** of the hard palate presents the following features:

1. **Incisive fossa**, a small pit anteriorly in the midline behind the incisor teeth, into which open the incisive canals. Each incisive canal/foramen (right and left) pierces the corresponding side and ascends into the corresponding nasal cavity. The incisive foramen transmits terminal parts of the nasopalatine nerve and greater palatine vessels.
2. **Greater palatine foramen**, one on each side, lies in the posterolateral corner of the hard palate medial to the last molar tooth. It transmits the greater palatine nerve and vessels.
3. **Lesser palatine foramina** (one to three in number) on each side are in the pyramidal process of palatine bone and are located just behind the greater palatine foramen. They provide passage to lesser palatine nerve and vessels.
4. **Posterior nasal spine** is a conical projection in the median plane on the sharp free posterior border of the hard palate.
5. **Palatine crest** is a curved ridge near the posterior border of the hard palate.
6. **Masticatory mucosa** is the mucous membrane lining the hard palate. In the anterior part, it is firmly united with the periosteum by multiple fibrous strands (Sharpey's fibres); hence, moving bolus of food does not displace the mucous membrane. It presents:
  - (a) *Transverse masticatory ridges* on either side of midline
  - (b) *Palatine raphe*, a narrow ridge of mucous membrane extending anteroposteriorly in the midline from a little papilla overlying the incisive fossa.

The hard palate is lined by keratinized stratified squamous epithelium.

## Arterial supply

This is by greater palatine arteries from the third part of the maxillary artery. Each artery emerges from greater palatine foramen and passes forwards around the palate (lateral to the nerve) to enter the incisive canal and pass up into the nose.

## Venous drainage

The veins of hard palate drain into the pterygoid venous plexus (mainly) and pharyngeal venous plexus.

### **Nerve supply**

The hard palate is supplied by greater palatine and nasopalatine nerves derived from pterygopalatine ganglion. *The greater palatine nerve supplies whole of the palate except anterior part of palate behind incisor teeth (the area of premaxilla), which is supplied by nasopalatine nerves.*

### **Lymphatic drainage**

The lymphatics from palate drain mostly into the upper deep cervical lymph nodes and few into retropharyngeal lymph nodes.

### **Soft palate AN 36.1**

The soft palate is a mobile muscular flap, which hangs down from the posterior border of the hard palate into the pharyngeal cavity like a curtain or velum. It separates the nasopharynx from oropharynx.

### **External features**

The soft palate presents the following external features:

1. **Anterior (oral) surface** is concave and marked by a median raphe.
2. **Posterior surface** is convex and continuous with the floor of the nasal cavity.
3. **Superior border** is attached to the posterior border of the hard palate.
4. **Inferior border** is free and forms the anterior boundary of the pharyngeal isthmus. A conical, small, tongue-like projection hanging down from its middle is called **uvula** .

On each side from the base of uvula, two curved folds of mucous membrane extend laterally and downwards:

- (a) The anterior fold merges inferiorly with the side of the tongue (at the junction of oral and pharyngeal parts) and is known as **palatoglossal fold** . The palatoglossal fold contains the palatoglossus muscle and forms the lateral boundary of the oropharyngeal isthmus.
- (b) The posterior fold merges inferiorly with the lateral wall of the

pharynx and is known as **palatopharyngeal fold** . The palatopharyngeal fold contains palatopharyngeus muscle and forms the posterior boundary of the tonsillar fossa.

### **Composition of soft palate (Fig. 14.23 ) AN 36.1**

The soft palate is made up of a fold of mucous membrane enclosing five pairs of muscles. The nasal surface of the soft palate is covered by *pseudostratified ciliated columnar epithelium* . The oral surface of the soft palate is thicker and lined by *nonkeratinized stratified squamous epithelium*.

**FIG. 14.23** ■ Microscopic features (composition) of soft palate.

The submucosa on both the surfaces contains mucous glands. The mucosa on the oral surface of the soft palate also contains some taste buds (especially in children) and lymphoid follicles.

## Muscles

The soft palate consists of the five pairs of muscles (Fig. 14.24 ), namely:

1. Tensor palati (tensor veli palatini)
2. Levator palati (levator veli palatini)
3. Palatoglossus
4. Palatopharyngeus
5. Musculus uvulae.

**FIG. 14.24** ■ Muscles of the soft palate.

### N.B.

All the muscles of soft palate are extrinsic *except* musculus uvulae, which are intrinsic.

The origin, insertion, and actions of muscles of the soft palate are given in Table 14.5 .

### TABLE 14.5

## Origin, insertion, and actions of muscle of the soft palate

Muscle	Origin	Insertion	Actions
<b><i>Tensor palati</i></b> (thin triangular muscle; Fig. 14.25 )	(a) Lateral aspect of the cartilaginous part of the auditory tube (b) Adjoining part of the greater wing of the sphenoid including its spine	Muscle descends, converges to form a tendon, which hooks around the pterygoid hamulus and then expands to form the palatine aponeurosis for attachment to: <ul style="list-style-type: none"> <li>• Posterior border of the hard palate</li> <li>• Inferior surface of the hard palate behind the palatine crest</li> </ul>	(a) Tightens soft palate (b) Helps in opening the auditory tube
<b><i>Levator palati</i></b> (a cylindrical muscle lying deep to tensor palati)	(a) Medial aspect of the cartilaginous part of the auditory tube (b) Adjoining part of the petrous temporal bone (inferior	Muscle runs downwards and medially and spreads out to be inserted on the upper surface of the palatine aponeurosis	(a) Elevates soft palate close the pharyngeal isthmus (b) Helps in opening the auditory tube

	surface of its apex anterior to carotid canal)		
<b><i>Musculus uvulae</i></b> (a longitudinal muscle strip, one on either side of the median plane within the palatine aponeurosis)	(a) Posterior nasal spine (b) Palatine aponeurosis	Mucous membrane of the uvula	Pulls the uvula forward to own side
<b><i>Palatoglossus</i></b>	Oral surface of the palatine aponeurosis	Descends into palatoglossal arch, to be inserted into the side of the tongue at the junction of its oral and pharyngeal parts	(a) Pulls up root of the tongue (b) Approximates the palatoglossal arches to close the oropharyngeal isthmus
<b><i>Palatopharyngeus</i></b> (consists of two fasciculi, which are separated by the levator palati)	(a) Anterior fasciculus: from posterior border of the hard palate (b) Posterior fasciculus: from palatine aponeurosis	Descends in the palatopharyngeal arch and inserted into the: <ul style="list-style-type: none"> <li>• Median fibrous raphe of pharyngeal wall</li> <li>• Posterior border of the lamina of thyroid cartilage</li> </ul>	Raises the wall of pharynx and larynx during swallowing

**FIG. 14.25 ■** Origin and course of the tensor palati muscles and formation of the palatine aponeurosis by the expansion of their tendons underneath the hard palate behind the palatine crest.

## Functions

1. Separates the oropharynx from nasopharynx during swallowing so that food does not enter the nose.
2. Isolates the oral cavity from oropharynx during chewing so that breathing is not affected.
3. Helps to modify the quality of voice, by varying the degree of closure of the pharyngeal isthmus.
4. Protects the nasal mucosa from damage during sneezing, by appropriately dividing and directing the blast of air through both nasal and oral cavities.
5. Prevents the entry of sputum into nose during coughing by directing it into the oral cavity.

## CLINICAL CORRELATION

**Effects of paralysis of soft palate:** The paralysis of the muscles of soft palate (due to lesion of vagus nerve) produces:

- (a) Nasal regurgitation of liquids
- (b) Nasal twang in voice
- (c) Flattening of the palatal arch on the side of the lesion
- (d) Deviation of uvula, opposite to the side of the lesion.

### Arterial supply

The soft palate is supplied by the following arteries:

1. Lesser palatine branches of greater palatine artery
2. Ascending palatine branch of the facial artery
3. Palatine branches of the ascending pharyngeal artery.

### Venous drainage

The venous blood from palate is drained into pharyngeal venous plexus and pterygoid venous plexus.

### Lymphatic drainage

The lymphatics from soft palate drain into retropharyngeal and upper deep cervical lymph nodes.

### Nerve supply

**Motor supply:** All the muscles of soft palate are supplied by the cranial root of accessory nerve via pharyngeal plexus except tensor palati, which is supplied by the nerve to medial pterygoid, a branch of the mandibular nerve.

**Sensory supply:** General sensations from palate are carried by:

- Lesser palatine nerves to the maxillary division of trigeminal nerve via pterygopalatine ganglion
- Glossopharyngeal nerve.

## CLINICAL CORRELATION

**Gag reflex:** It is a *protective reflex* characterized by the elevation of the palate and contraction of the pharyngeal muscles with associated *retching*

and gagging in response to stimulation of the mucous membrane of the oropharynx. It occurs when the palate, tonsil, posterior part of the tongue, or posterior pharyngeal wall are touched by unfamiliar objects such as swab and spatula. The afferent limb of the reflex is provided by the glossopharyngeal nerve and efferent limb by the vagus nerve.

### Development of the palate

The **primary palate** (also called **premaxilla**) develops from the frontonasal process. The secondary palate develops from the palatine process of the maxillary processes.

Two palatine processes (one on each side) develop from the inner aspects of the maxillary processes and fuse in the midline to form the **secondary palate**, which is soon joined by nasal septum (Fig. 14.26).

**FIG. 14.26 ■** Development of the palate: ( **A** ) separation of the nasal cavities from each other and from oral cavity; ( **B** ) embryological subdivisions of the palate and their source of development.

The **hard palate** is formed by the fusion of the primary palate with the secondary palate. The incisive foramina mark the junction of the two components of the palate. The fusion takes place from anterior to posterior parts.

The soft palate develops from two folds that grow posteriorly from the

posterior edge of the palatal processes. Thus, uvula is the last structure to develop. The two folds unite to form the soft palate.

## CLINICAL CORRELATION

**Cleft palate** : The defective fusion of various segments of the palate gives rise to clefts in the palate. These vary considerably in degree, leading to varieties of cleft palate, namely:

### (a) **Complete cleft**

- *Unilateral complete cleft* occurs if maxillary process on one side does not fuse with the premaxilla. It is always associated with the cleft lip.
- *Bilateral complete cleft* occurs if both the maxillary processes fail to fuse with the premaxilla. In this type, secondary palate is divided into two equal halves by a median cleft with an anterior V-shaped cleft separating the premaxilla completely.

### (b) **Incomplete or partial cleft**: The following stages may occur:

- *Bifid uvula* – cleft involving only uvula; it is of no clinical importance
- *Cleft of soft palate* – involving uvula and soft palate
- *Cleft of soft palate* – extending into the hard palate

For details, see *Textbook of Clinical Embryology* , 4ed. by Vishram Singh.

## Golden Facts to Remember

• <b>Killian's dehiscence</b>	A weak area in the posterior wall of pharynx between thyropharyngeus and cricopharyngeus, the two parts of inferior constrictor muscle
• <b>Principal artery of tonsil</b>	Tonsillar branch of the facial artery
• <b>Common source of bleeding after tonsillectomy</b>	Paratonsillar vein
• <b>Tonsillar lymph node</b>	Jugulodigastric lymph node
• <b>Most common variety of cleft</b>	Unilateral cleft palate involving the hard palate

<b>palate</b> • <b>Largest tonsils</b>	Palatine tonsils
• <b>Quinsy</b>	Chronic infection of peritonsillar space
• <b>Coffin corner of mouth</b>	Alveololingual/linguo-tonsillar sulcus

## CLINICAL CASE STUDY

An 8-year-old boy was taken by his parents to the physician and complained that their son was suffering from recurrent attacks of sore throat, and for the past few days, he has difficulty in swallowing and feeling pain not only in his throat but also in his ears. On examination of oropharynx, the physician found that both the tonsils were enlarged and almost touching each other in the midline. The palpation of cervical lymph nodes revealed enlarged and tender tonsillar nodes. The boy was diagnosed as a case of **tonsillitis**.

### Questions

1. What is meant by the term tonsil?
2. What are tonsillar lymph nodes?
3. What was the cause of earache?

### Answers

1. Unless otherwise stated, reference to tonsil always refers to the palatine tonsil.
2. Jugulodigastric lymph nodes.
3. The tonsil is supplied by the glossopharyngeal nerve and tympanic branch of this nerve supplies mucous membrane of the middle ear (tympanic cavity). Therefore, pain of tonsillitis is referred to the ear.

---

# Chapter 15: Larynx

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the larynx under the following headings: (a) morphology, (b) structure of wall, (c) nerve supply, and (d) blood supply. **AN 38.1**
- Describe the boundaries and clinical significance of piriform fossa. **AN 38.3**
- Describe the anatomical aspects of laryngitis. **AN 38.2**
- Enumerate the intrinsic muscles of larynx. Give the origin, insertion, nerve supply, and actions of cricothyroid and posterior cricoarytenoid muscles only.
- Describe the actions of intrinsic and extrinsic muscles of larynx. **AN 38.1**
- Write short notes on: (a) laryngeal inlet, (b) piriform fossa, (c) vocal cords, and (d) cricothyroid muscle.
- Enumerate: (a) cartilages of larynx and (b) subdivisions of laryngeal cavity as seen in coronal section.
- Give the anatomical basis of: (a) vocal nodules/singer's nodules, (b) laryngocele, and (c) cadaveric position of vocal cords.
- Draw the labelled diagram to show: (a) laryngoscopic view of laryngeal cavity and (b) coronal section of laryngeal cavity.
- Describe the anatomical basis of recurrent laryngeal nerve. **AN 38.3**

The larynx (Greek, larynges = upper wind pipe) is the upper expanded part of the lower respiratory tract, which is modified for producing voice; hence, it is also called **voice box/organ of phonation**. It acts as a sphincter at the inlet of lower respiratory tract to protect the trachea and the bronchial tree

from entry of any material other than the air. If this protective role is deranged, laryngeal incompetence results and food and fluid may be aspirated into trachea. Further, the upward and downward movements of the larynx help in swallowing.

The **functions** of larynx include the following:

1. Phonation
2. Respiration
3. Protection
4. Deglutition.

### **N. B.**

Although phonation is important in humans, primary (most important) function of the larynx is to provide protection for the lower respiratory tract. The phonation has developed later with evolution and is related to the motor speech area of the brain.

### **Location and extent**

The larynx is situated in the anterior midline of the upper part of the neck above trachea in front of laryngopharynx. It extends from the root of the tongue to the trachea and lies in front of the 3rd, 4th, 5th, and 6th cervical vertebrae. However, in children and females, it lies at a little higher level.

### **Size**

The average measurements of larynx in males and females are as follows:

	<b>Vertical</b>	<b>Transverse</b>	<b>Anteroposterior</b>
Male	44 mm	43 mm	36 mm
Female	36 mm	41 mm	26 mm

Till puberty, the size of larynx in both males and females is more or less same, but at puberty, male larynx grows rapidly and becomes larger than the female larynx. The pubertal growth of the larynx in adult females does not differ much from a child; for this reason, the pitch of voice is high in both females and children. In males, the characteristic pubertal growth of angle of the thyroid cartilage (*Adam's apple*) makes the voice louder and low pitched.

### **Skeleton (Fig. 15.3 ) AN 38.1**

The skeletal framework of the larynx consists of a series of cartilages, which

are connected to one another by ligaments, and fibrous membranes, and moved by a number of muscles.

The lumen of larynx is kept patent by its cartilaginous framework, because in adults, the rate of breathing is approximately 15 times per minute.

### **N.B.**

The hyoid bone is closely associated to the larynx with distinctive functional roles. However, it is usually considered as a separate structure.

## **Cartilages**

The larynx is composed of nine cartilages, of which three are unpaired and three are paired:

1. **Unpaired cartilages:** The unpaired cartilages are large and comprise:
  - (a) Thyroid
  - (b) Cricoid
  - (c) Epiglottis.
2. **Paired cartilages:** The paired cartilages are small and comprise:
  - (a) Arytenoid
  - (b) Corniculate
  - (c) Cuneiform

The **principal cartilages of the larynx** are cricoid, thyroid, and two arytenoids ([Fig. 15.1](#) ).

#### A. THYROID CARTILAGE

#### B. CRICOID CARTILAGE

#### C. ARYTENOID CARTILAGE

**FIG. 15.1 ■** Principal cartilages of the larynx.

### Thyroid cartilage

It is the most prominent and acts as a shield to protect the larynx from the front. It consists of two quadrilateral laminae, which meet in front at an angle called **thyroid angle**, which is acute in males and obtuse in females (like subpubic angle). The angle measures 90 degrees in males and 120 degrees in females. It is located at the level of C4-C5 vertebra.

The thyroid angle is prominent in males and it is responsible for prominence on the front of the neck called **Adam's apple**.

The posterior surface of the thyroid cartilage in the median plane provides attachment (from above downward) to the following structures (**Fig. 15.2 A**):

1. Thyroepiglottic ligament
2. A pair of vestibular ligaments
3. A pair of vocal ligaments.

**FIG. 15.2 ■** Attachments of the muscles and ligaments on the thyroid cartilage: ( **A** ) on the posterior surface; ( **B** ) on the outer surface and posterior border of the lamina.

The **posterior border of each lamina** is free and prolonged upwards and downwards as *superior and inferior horns/cornu*. It provides conjoint insertion to the following three muscles (**Fig. 15.2 B**):

1. Palatopharyngeus
2. Salpingopharyngeus
3. Stylopharyngeus.

The **outer surface of each lamina** presents an oblique line and provides attachment to the following three muscles; from above downwards and from medial to lateral sides, these are (Fig. 15.2 B) as follows:

1. Thyrohyoid
2. Sternothyroid
3. Inferior constrictor (thyropharyngeus part only).

### **Cricoid cartilage**

It is shaped like a signet-ring with a narrow anterior arch and a broad posterior lamina. The cricoid cartilage is situated at the level of C6 vertebra and **completely encircles the lumen of the larynx** . It is considered as the **foundation stone of the larynx** . The posterior surface of lamina presents a median ridge and two depressed areas on each side of this ridge.

### **Epiglottis (Fig. 15.3 )**

It is leaf-like and extends up behind the hyoid bone and the base of the tongue. Its broad upper end is free and forms the upper boundary of the laryngeal inlet, whereas the lower end (stalk) is pointed and connected to the posterior surface of the angle of the thyroid by *thyroepiglottic ligament* .

**FIG. 15.3 ■** Skeleton of the larynx: ( **A** ) anterior view; ( **B** ) posterior view; and ( **C** ) lateral view.

The anterior surface of epiglottis is connected with the base of the tongue by median and lateral glossoepiglottic folds. The depression on each side of the median fold is called **vallecula** .

The posterior surface of epiglottis presents a tubercle in its lower part.

### N.B.

The epiglottis is rudimentary in human beings, but in macrosomatic animals, it is elongated and extends beyond the soft palate in the nasopharynx.

### Arytenoid cartilages

The paired arytenoid cartilages articulate with the lateral parts of the upper border of cricoid lamina. Each arytenoid cartilage is pyramidal and presents an apex, base, three surfaces (posterior, anterolateral, and medial), and two processes – muscular and vocal ([Fig. 15.1](#)).

The **muscular process** projects laterally and backwards, whereas the **vocal process** is directed forwards.

The **base** of arytenoid cartilage is concave and articulates with the upper border of the lamina of cricoid cartilage. The base is prolonged anteriorly to form the *vocal process* and laterally to form the *muscular process*.

The **apex** is curved posteromedially and articulates with the corniculate cartilage.

### Corniculate cartilages (of Santorini)

These are two small conical nodules, which articulate with the apices of the arytenoid cartilages. They are directed posteromedially and lie in the posterior parts of the aryepiglottic folds.

### Cuneiform cartilages (of Wrisberg)

They are tiny rod-shaped cartilages lying in the posterior parts of the aryepiglottic folds just above the corniculate cartilages.

### Types of laryngeal cartilages

The thyroid, cricoid, and basal parts of arytenoid cartilages are composed of **hyaline cartilage** and tend to ossify after 25 years of age and can be seen in radiographs.

The apices of arytenoid cartilages and other cartilages – epiglottis, corniculate, and cuneiform – are made up of **elastic cartilage** and do not ossify.

### Joints

The laryngeal joints include paired cricothyroid, cricoarytenoid, and

arytenocorniculate joints (Fig. 15.4 ).

**FIG. 15.4** ■ Joints of the larynx.

### **Cricothyroid joint**

It is a plane synovial joint between the inferior cornu of the thyroid cartilage and side of cricoid cartilage. The recurrent laryngeal nerve enters the larynx very close to this joint. This joint permits two types of movements, namely:

1. **Rotatory movement** , in which cricoid rotates on the inferior cornua of the thyroid cartilage around a transverse axis, which passes transversely through both cricothyroid joints.
2. **Gliding movement** , in which cricoid glides, to a limited extent, in different directions on the thyroid cornua.

### **Cricoarytenoid joint**

It is a tiny plane synovial joint between the base of the arytenoid and lateral part of the upper border of the lamina of cricoid cartilage. This joint permits two types of movements, namely:

1. **Rotatory movement** , in which arytenoid cartilage moves around a vertical axis, thus abducting or adducting the vocal cords.
2. **Gliding movement** , in which one arytenoid glides towards the other or away from it, thus closing or opening the posterior part of glottis.

### **Arytenocorniculate joint**

It is a synovial joint between the arytenoid and corniculate cartilages. It is of no functional significance.

### **Ligaments and membranes**

The skeletal framework of the larynx is interconnected by a number of ligaments and fibrous membranes. The most significant fibrous membranes connecting skeletal framework of the larynx are thyrohyoid, cricothyroid, quadrangular, and cricovocal membranes.

### **Extrinsic ligaments and membranes**

The **extrinsic ligaments and membranes** are outside the inner tube of the fibroelastic tissue of laryngeal cavity ([Fig. 15.3](#)):

1. **Thyrohyoid membrane and ligaments:** The thyrohyoid membrane extends from the upper border of the thyroid cartilage to the upper border of the hyoid bone. It ascends behind the concave posterior surface of the hyoid bone. Between posterior aspect of hyoid and membrane lies the *subhyoid bursa* . In the median and lateral parts, the thyrohyoid membrane thickens to form *median and lateral thyrohyoid ligaments*. The lateral thyrohyoid ligament on each side contains a small nodule of elastic cartilage called **cartilago triticea** . The thyrohyoid membrane is pierced on either side by internal laryngeal nerve and superior laryngeal vessels.
2. **Cricotracheal ligament:** It connects the cricoid cartilage with the first tracheal ring.
3. **Thyroepiglottic ligament:** It attaches the lower narrow end of epiglottis to the posterior surface of thyroid angle.
4. **Hyoepiglottic ligament:** It connects the posterior aspect of hyoid with the anterior surface of the upper end of epiglottis.
5. **Cricothyroid ligament:** It connects the lower border of the thyroid cartilage to the cricoid cartilage in the midline.

## **Intrinsic ligaments and membranes**

The ***intrinsic ligaments and membranes*** are the parts of a broad sheet of fibroelastic tissue, which forms the inner tube of the laryngeal cavity outside its mucous lining. This fibroelastic tube is, however, interrupted on each side by the sinus of the larynx. The part above the sinus is called **quadrate** or **quadrangular membrane** and part below the sinus is called **cricovocal membrane** or **conus elasticus** ([Fig. 15.5](#)):

1. **Cricovocal membrane** extends upwards and medially from the upper border of the arch of the cricoid cartilage. Its upper edge is free and attached anteriorly to the posterior surface of the thyroid cartilage and posteriorly to the vocal process of the arytenoid cartilage. It is slightly thickened to form the **vocal ligament**. The fold of mucous membrane over this ligament forms the **vocal fold**.
2. **Vocal ligament** is made up of yellow elastic tissue and extends anteroposteriorly from posterior surface of the thyroid cartilage to the vocal process of arytenoid cartilage.
3. **Quadrangular membrane** extends from sides of epiglottis to the arytenoid. Its lower edge is free and attached anteriorly to the posterior surface of the thyroid cartilage (above the cricothyroid membrane) and posteriorly to the lateral surface of the arytenoid cartilage (in front of muscular process). Its lower edge is thickened to form the **vestibular ligament**.
4. **Vestibular ligament** is made up of fibrous tissue and extends anteroposteriorly from posterior surface of the thyroid cartilage to the lateral surface of the arytenoid cartilage.

**FIG. 15.5** ■ Sagittal section of the larynx showing ligaments and membranes. Note the location of quadrangular and cricovocal membranes.

Extrinsic and intrinsic membranes and ligaments are summarized in [Table 15.1](#).

**TABLE 15.1**

### Extrinsic and intrinsic membranes and ligaments of the larynx

	<b>Extrinsic</b>	<b>Intrinsic</b>
<b>Membranes</b>	<ul style="list-style-type: none"> <li>• Thyrohyoid</li> <li>• Cricotracheal</li> </ul>	<ul style="list-style-type: none"> <li>• Cricovocal (conus elasticus)</li> <li>• Quadrate/quadrangular</li> </ul>
<b>Ligaments</b>	<ul style="list-style-type: none"> <li>• Median and lateral thyrohyoid</li> <li>• Cricothyroid</li> </ul>	<ul style="list-style-type: none"> <li>• Vocal</li> <li>• Vestibular</li> </ul>

## Muscles

They are of two types: extrinsic and intrinsic.

### Extrinsic muscles

They attach the larynx to the surrounding structures and are responsible for the movement of the larynx as a whole.

All the extrinsic muscles are paired and include:

1. Palatopharyngeus
2. Salpingopharyngeus
3. Stylopharyngeus
4. Thyrohyoid
5. Sternothyroid.

All these muscles elevate the larynx except sternothyroid, which depresses the larynx.

The first three muscles are discussed in detail in [Chapter 14](#) and the last two in [Chapter 6](#).

### Intrinsic muscles (Fig. 15.6 )

They attach the laryngeal cartilages to each other and are responsible for their movements. Their main functions are to:

- (a) Open or close the laryngeal inlet
- (b) Adduct and abduct the vocal cords
- (c) Increase or decrease the tension of the vocal cords.

**FIG. 15.6 ■** Intrinsic muscles of the larynx: ( **A** ) lateral view; ( **B** ) posterior view; and ( **C** ) direction of pull of some intrinsic muscles. VP, vocal process of arytenoid.

Thus, according to their actions, intrinsic muscles of the larynx are arranged into the following groups.

### **Muscles that open or close the laryngeal inlet**

1. Oblique arytenoids 2. Aryepiglotticus	Closes the inlet of larynx.
3. Thyroepiglotticus: opens the inlet of larynx.	

### **Muscles that abduct or adduct the vocal cords**

1. Posterior cricoarytenoids abduct the vocal cords.
2. Lateral cricoarytenoids adduct the vocal cords.
3. Transverse arytenoid adducts the vocal cords.

### **Muscles that increase or decrease tension of vocal cords**

1. Cricothyroid tenses the vocal cords
2. Vocalis tenses the vocal cords
3. Thyroarytenoid relaxes the vocal cords

### **Intrinsic muscles of larynx**

All the intrinsic muscles of the larynx are paired except transverse arytenoid, which is unpaired.

The origin and insertion of the intrinsic muscles are presented in [Table 15.2](#)

**TABLE 15.2**

### **Origin and insertion of intrinsic muscles of the larynx**

<b>Muscle</b>	<b>Origin</b>	<b>Insertion</b>
<b><i>Cricothyroid</i></b> (a triangular muscle)	Anterolateral part of the arch of the cricoid cartilage	Fibres pass backwards and upwards to be inserted into:  (a) Inferior cornu (b) Adjacent part of the lower border of lamina of the thyroid cartilage
<b><i>Oblique arytenoid</i></b>	Muscular process of one arytenoid cartilage	Apex of opposite arytenoid cartilage
<b><i>Aryepiglotticus</i></b> (a slender elongated slip of the upper fibres of oblique arytenoid, which continue in aryepiglottic fold to reach the margin of epiglottis)	Muscular process of arytenoid cartilage	Margin of epiglottis
<b><i>Transverse arytenoid</i></b> (rectangular muscle) connects the posterior surfaces of two arytenoid cartilages	Posterior surface of one arytenoid	Posterior surface of another arytenoid
<b><i>Lateral cricoarytenoid</i></b> (a triangular muscle)	Lateral part of upper border of cricoid arch	Front of muscular process of the arytenoid cartilage
<b><i>Posterior cricoarytenoid</i></b> (a triangular muscle)	Posterior surface of cricoid lamina lateral to median ridge	Back of muscular process of the arytenoid cartilage
<b><i>Thyroarytenoid</i></b>	Posterior aspect of angle	Anterolateral surface of the

	of the thyroid cartilage	arytenoid cartilage
<b>Thyroepiglotticus</b> (some upper fibres of thyroarytenoid curve upwards into aryepiglottic fold to reach the margin of epiglottis)	Posterior aspect of angle of the thyroid cartilage	Margin of epiglottis

The students need not remember the origin and insertion of all the intrinsic muscles. However, they should know about a few muscles in detail. These are described in following text.

### Cricothyroid muscle

It is the only muscle of the larynx, which lies on the **external surface of the larynx** .

It is a small *fan-shaped* muscle, which arises from the *anterolateral aspect of the cricoid*. After origin, its fibres pass backwards and upwards, to be inserted into the inferior cornu and adjacent lower border of the lamina of the thyroid cartilage. It is supplied by **external laryngeal nerve** . Its contraction makes the thyroid cartilage to tilt slightly downwards and forwards at the cricothyroid joints, thereby *lengthening and tensioning the vocal cord* (Fig. 15.7 ). It also helps in *adduction of vocal cord* which is essential for phonation.

**FIG. 15.7** ■ Action of the cricothyroid muscle.

The whole thyroid cartilage can move downwards and forwards over the cricoid like the visor of a knight's helmet (Grant).

## CLINICAL CORRELATION

**Tuning fork of larynx:** The cricothyroid is an important muscle for the *tone and pitch of the voice*. When sound is about to be produced, it tenses the vocal cord and makes it ready to vibrate like a tuning fork. Hence, it is also known as the **tuning fork of larynx**. Paralysis of this muscle following external laryngeal nerve lesion alters the voice quite significantly and is especially noticeable in singers.

### Vocalis muscle

The vocalis is a paired laryngeal muscle lying parallel to vocal ligaments. Together with vocal ligament, it forms main component of vocal cord.

- It is considered to be *detached medial part of the thyroarytenoid* and lies within the vocal fold just lateral and cranial to the vocal ligament. It arises from the *thyroid angle and anterior part of vocal ligament* and inserted into the lateral surface of the vocal process arytenoid cartilage ([Fig. 15.8](#)). On its contraction, the anterior part of vocal ligament tenses, whereas its posterior part is relaxed.
- It is supplied by the recurrent laryngeal nerve and few fibres of external laryngeal nerve.
- It *tenses the anterior part and relaxes the posterior part of the vocal cord*.

**FIG. 15.8 ■** Origin and insertion of the vocalis muscle.

### **N.B.**

The segmental tension of vocal ligament helps in the **modulation of voice** like the fingers of a violinist and responsible for high-pitched voice.

### **Posterior cricoarytenoid**

- It is a **triangular muscle**, which arises from the **posterior surface of the cricoid lamina** lateral to its median ridge. After origin, the fibres pass upwards and laterally to be inserted into the back of the muscular process of the arytenoid.
- It is supplied by recurrent laryngeal nerve.
- The posterior cricoarytenoid **abducts the vocal cords** .

### **CLINICAL CORRELATION**

**Safety muscles of larynx:** The posterior cricoarytenoid muscles are the only intrinsic muscles of the larynx, which abduct the vocal cords to allow entry of air through rima glottidis in the respiratory tract below it.

When posterior cricoarytenoids contract, muscular processes of both the arytenoid cartilages rotate medially. As a result, the vocal processes rotate laterally (abducting vocal cords) providing wide diamond-shaped opening of the glottis.

If posterior cricoarytenoids are paralysed, the adductor muscles (of vocal cords) take the upper hand and the person might die because of lack of air. Hence, the posterior cricoarytenoid muscles are called *safety muscles of the larynx*.

### Nerve supply

All the intrinsic muscles of the larynx are supplied by recurrent laryngeal nerve *except* cricothyroid, which is supplied by the external laryngeal nerve.

### CLINICAL CORRELATION

- **Damage of external laryngeal nerve:** *If it is damaged*, there is some weakness of phonation due to loss of tightening effect of cricothyroid muscle on the vocal cords.
- **Damage of recurrent laryngeal nerve:** *It is often damaged*, accidentally during partial thyroidectomy:
  - ϕ(a) *If damaged unilaterally*, the vocal cord on the affected side lies in paramedian position (between abduction and adduction) and does not vibrate. But usually the other cord is able to compensate and the phonation is not much affected. The sound (normal) vocal cord moves freely and even cross the midline to meet the paralysed vocal cord.
  - ϕ(b) *If damaged bilaterally*, both the vocal cords lie in the paramedian position with consequent loss of phonation and difficulty in breathing. **AN 38.3**
- **Damage of both recurrent and external laryngeal nerves:** *If the recurrent and external laryngeal nerves are involved on both sides*, the vocal cords are further abducted and fixed because of paralysis of all intrinsic muscles of the larynx. This is known as the *cadaveric position of vocal cords* or *rima glottidis*.

### N.B.

Exceptions :

- The cricothyroid is the *only* muscle lying on the outer aspect of the

- The cricothyroid is the *only* muscle lying on the outer aspect of the larynx.
- All the intrinsic muscles of the larynx are paired *except* transverse arytenoid (interarytenoid), which is unpaired.
- All the intrinsic muscles of larynx adduct the vocal cords *except* posterior cricoarytenoid, which abduct the vocal cords.

## Cavity of larynx

It extends from inlet of larynx, where it communicates with the lumen of laryngopharynx to the lower border of the cricoid cartilage, where it is continuous with the lumen of the trachea. The anterior wall of laryngeal cavity is longer than the posterior wall.

**Laryngeal inlet** is obliquely placed, sloping downwards and backwards. It opens into the laryngopharynx.

## Boundaries

*Anterior:* Epiglottis

*Posterior:* Interarytenoid fold of the mucous membrane

*Lateral (on each side):* Aryepiglottic fold of the mucous membrane

## CLINICAL CORRELATION

### Laryngitis

It is inflammation of larynx (voice box) due to infection, irritation, and overuse. Infection is mostly viral.

### Clinical features

- A feeling of tickling in throat
- Dry cough with constant urge to clear throat
- Impaired voice or hoarseness of voice ranging from mild hoarseness to total loss of voice.

### Laryngeal obstruction

The mucous membrane of the superior part of larynx is very sensitive. When foreign body (a piece of food or a drop of water, etc.) enters into the laryngeal inlet, it causes immediate explosive coughing and the foreign body is expelled out. If this reflex is slowed or absent as in neurological lesion or

after consuming alcohol, a foreign body (e.g., piece of meat) may enter the laryngeal cavity and cause choking (i.e., laryngeal obstruction). Choking by food is a common cause of laryngeal obstruction and asphyxia. If foreign body is not dislodged and expelled out immediately by Heimlich manoeuvre, person will die within minutes, almost certainly before there is time to take him or her to the hospital. Hence, it is also called '*cafe coronary*' phenomenon .

The **Heimlich manoeuvre** is performed as follows (Fig. 15.9):

Stand behind the victim, pass your arms under his or her arms, place hands in front of the victim's epigastrium with one hand formed into a fist and the other hand lying over it. Now give three or four abdominal thrusts directed upwards and backwards. By doing this, the residual air in the lungs is squeezed up in trachea and larynx with force, dislodging foreign body and thus relieving laryngeal obstruction (choking). The foreign body is either expelled itself or removed.

**FIG. 15.9** ■ Heimlich manoeuvre. Figure in the inset shows the position of hands in the epigastric region of the victim.

### **Subdivisions of the laryngeal cavity**

The laryngeal cavity is divided into three parts by *two pairs of vestibular and*

*vocal folds* (Fig. 15.10 ). Within the laryngeal cavity, **two pairs of folds** of the mucous membrane extend (on each side) posteroanteriorly from arytenoid cartilage to the thyroid cartilage:

1. The upper folds are produced by vestibular ligament and called **vestibular folds** or **false vocal cords** . The space between vestibular folds is called **rima vestibuli** . When the vestibular folds come together, they prevent food and liquids from entering the larynx and air from leaving the lungs, as when a person holds his or her breath.
2. The lower folds are produced by the vocal ligaments and vocalis muscle, and called **vocal folds** or **true vocal cords**. They extend from the middle of the thyroid angle to the vocal processes of arytenoids.

**FIG. 15.10** ■ Coronal section of the laryngeal cavity showing its subdivisions. A, vestibule; B, ventricle of the larynx; C, infraglottic compartment.

***The three parts of laryngeal cavity are:***

1. **Vestibule (supraglottic compartment)** : It extends from laryngeal inlet to the vestibular folds.
  - Its **anterior wall** is formed by the mucous membrane covering the posterior surface of epiglottis, **posterior wall** by the mucous membrane covering the apices of arytenoid cartilages, and corniculate cartilages, and **sides** by aryepiglottic folds.
  - The aryepiglottic folds separate the vestibule from piriform recesses.
2. **Ventricle or sinus of the larynx (rima glottidis)**: It is the deep elliptical space between vestibular and vocal folds. On each side, a narrow blind diverticulum of the mucous membrane extends posterosuperiorly between the vestibular fold and lamina of the thyroid cartilage, called **sacculus of the larynx** . It is provided with the mucous glands, whose secretions lubricate the vocal cords. Hence, it is also termed *oil can of the larynx* .
  - The rima glottidis is the narrowest part of the laryngeal cavity.
3. **Infraglottic compartment**: It extends from vocal folds to the lower border of the cricoid cartilage.

## CLINICAL CORRELATION

**Laryngocele:** If air pressure in the laryngeal sinus is raised too much as in trumpet players, glass blowers or weight lifters, the sacculus dilates to produce an air-filled cystic swelling called *laryngocele* (Fig. 15.11 ). The laryngocele may be internal, when it is located within the larynx or external, when distended sacculus herniates through the thyrohyoid membrane and comes outside the larynx.

**FIG. 15.11 ■ Laryngocele.**

### **N.B.**

Piriform Fossa (Fig. 15.10 ) It is a deep fossa/recess in the wall of laryngopharynx lying on either side of the laryngeal inlet. It is bounded:

Medially by: Aryepiglottic fold. Laterally by: Thyroid cartilage and thyroid membrane.

The mucous membrane lining medial and lateral walls meet inferiorly to form floor of the fossa. Just underneath floor lies inter laryngeal nerve and vessels. For details see Chapter 14, page 197.

### **Mucous membrane**

The mucous membrane of the larynx is loosely attached, *except* over the posterior surface of the epiglottis, true vocal cords, corniculate and cuneiform cartilages where it is firmly adherent.

The whole of the laryngeal cavity is lined by *ciliated columnar epithelium* except the anterior surface and upper half of the posterior surface of the epiglottis, upper parts of aryepiglottic folds and vocal folds, which are lined by *stratified squamous epithelium* .

The *mucous glands* are distributed all over the mucous lining. They are particularly numerous on the posterior surface of the epiglottis, posterior

parts of aryepiglottic folds and in the saccules. There are no mucous glands in the vocal folds.

### N.B.

The mucosa (lined by stratified squamous epithelium) lining the vocal cords is firmly adhered to the vocal ligaments and there is no intervening submucosa. This accounts for the pearly white avascular appearance of vocal cords.

### CLINICAL CORRELATION

**Laryngitis AN 38.2** : It is an inflammation of larynx due to infection or overuse. The vocal cords become inflamed. This makes the vocal cords swell. They are not able to vibrate normally when air passes over them. As a result, the voice becomes hoarse and painful.

The oedema of larynx usually does not involve the true vocal cords because there is no submucous tissue.

### Nerve supply of the larynx

**Motor nerve supply** : It is provided by recurrent laryngeal and external laryngeal nerves.

**Sensory nerve supply** : The mucous membrane of larynx above the vocal folds is supplied by the *internal laryngeal nerve* , whereas below the vocal folds by the *recurrent laryngeal nerve* .

### CLINICAL CORRELATION

If *internal laryngeal nerve* is damaged , there is anaesthesia of the mucous membrane in the supraglottic portion and loss of protective cough reflex. As a result, the foreign bodies can readily enter the larynx.

### Arterial supply of the larynx

The arterial supply of larynx is as follows:

1. **Above the vocal fold** by *superior laryngeal artery* , a branch of superior thyroid artery.
2. **Below the vocal fold** by *inferior laryngeal artery* , a branch of inferior thyroid artery.

### N.B.

Rima glottidis has dual blood supply (vide supra).

### **Venous drainage of the larynx**

The veins draining the larynx accompany the arteries. These are as follows:

1. **Superior laryngeal vein**, which drains into the superior thyroid vein.
2. **Inferior laryngeal vein**, which drains into the inferior thyroid vein.

### **Lymphatic drainage of the larynx**

The lymphatics from:

- (a) **Above the vocal cords** pierce the thyrohyoid membrane, run along superior thyroid vessels and drain into upper deep cervical lymph nodes (anterosuperior group).
- (b) **Below the vocal cords** pierce the cricothyroid membrane and go to the prelaryngeal and pretracheal nodes, and then drain into lower deep cervical lymph nodes (posteroinferior group).

### **Phonation**

The phonation is the production of vocal sounds for a speech. It can be high-pitched or low-pitched.

### **Rima glottidis and phonation**

It is the narrowest anteroposterior cleft of the laryngeal cavity. The anteroposterior diameter of glottis is 24 mm in adult males and 16 mm in adult females.

### **Boundaries**

*In front:* Angle of thyroid cartilage

*Behind:* Interarytenoid folds of the mucous membrane

*On each side:* Vocal fold in anterior three-fifth and vocal process of arytenoid cartilage in the posterior two-fifth.

### **Subdivisions of rima glottidis**

The rima glottidis is divided into the following two parts:

1. **Intermembranous part** in the anterior three-fifth, between the

vocal cords.

2. **Intercartilaginous part** in the posterior one-fifth, between the vocal processes of arytenoid cartilage.

### **Shape of rima glottidis (Fig. 15.12 )**

The size and shape of glottis vary with the movements of the vocal cords:

- **In quiet breathing**, the intermembranous part is triangular and intercartilaginous part is rectangular. As a whole, the glottis is *pentagonal* .
- **In full inspiration**, the glottis widens and becomes *diamond shaped* because of abduction of vocal cords.
- **During high-pitched voice**, the rima glottidis is reduced to a *linear chink* , because of adduction of both intermembranous and intercartilaginous parts.
- **During whispering**, the intermembranous part is highly adducted and intercartilaginous part is separated by triangular gap, thus rendering an *inverted funnel* shape to the rima glottidis.

**FIG. 15.12** ■ Variations in the size and shape of rima glottidis during different movements of the vocal cords.

### **Mechanism of phonation AN 38.2**

The phonation (speech) is produced by the vibrations of the vocal cords. The greater the amplitude of vibration, the louder is the sound.

The larynx is like a wind instrument. The voice is produced in the following manner:

1. Vocal cords are kept adducted.
2. Infraglottic air pressure is generated by the exhaled air from lungs by the contraction of abdominal, intercostal, and other expiratory muscles.
3. Force of air opens the cords and is released as small puffs.
4. As the moving air passes through the vocal cords, it makes them to vibrate producing sound.
5. Sound is amplified by mouth, pharynx, oesophagus, and nose.
6. Sound is converted into speech by the modulatory actions of lips, tongue, palate, pharynx, and teeth.

### N.B.

- The *vowels* are voiced in the larynx because of vibration of vocal folds, whereas *consonants* are produced by the intrinsic muscles of the tongue.
- The *loudness of sound* depends on the amplitude of vibrating vocal folds, whereas pitch depends on the frequency with which the vocal folds vibrate. Because the vocal cords are usually longer in males than females, they vibrate with greater amplitude but with lower frequency. Hence, voice of males is louder but low pitched.

### CLINICAL CORRELATION

**Vocal nodules (singer's or screamer's nodules):** During vibration, the area of maximum contact between the vocal cords is at the junction of their anterior one-third and posterior two-third and thus subject to maximum friction. Hence, in individuals, who overuse their voice, such as teachers and pop singers, the inflammatory nodules develop at these sites called *vocal nodules*. They are bilateral and symmetrical, and vary in size from that of pinhead to a split pea. In early stages, they are soft, reddish, and oedematous but later become greyish or whitish in colour ([Fig. 15.13](#)).

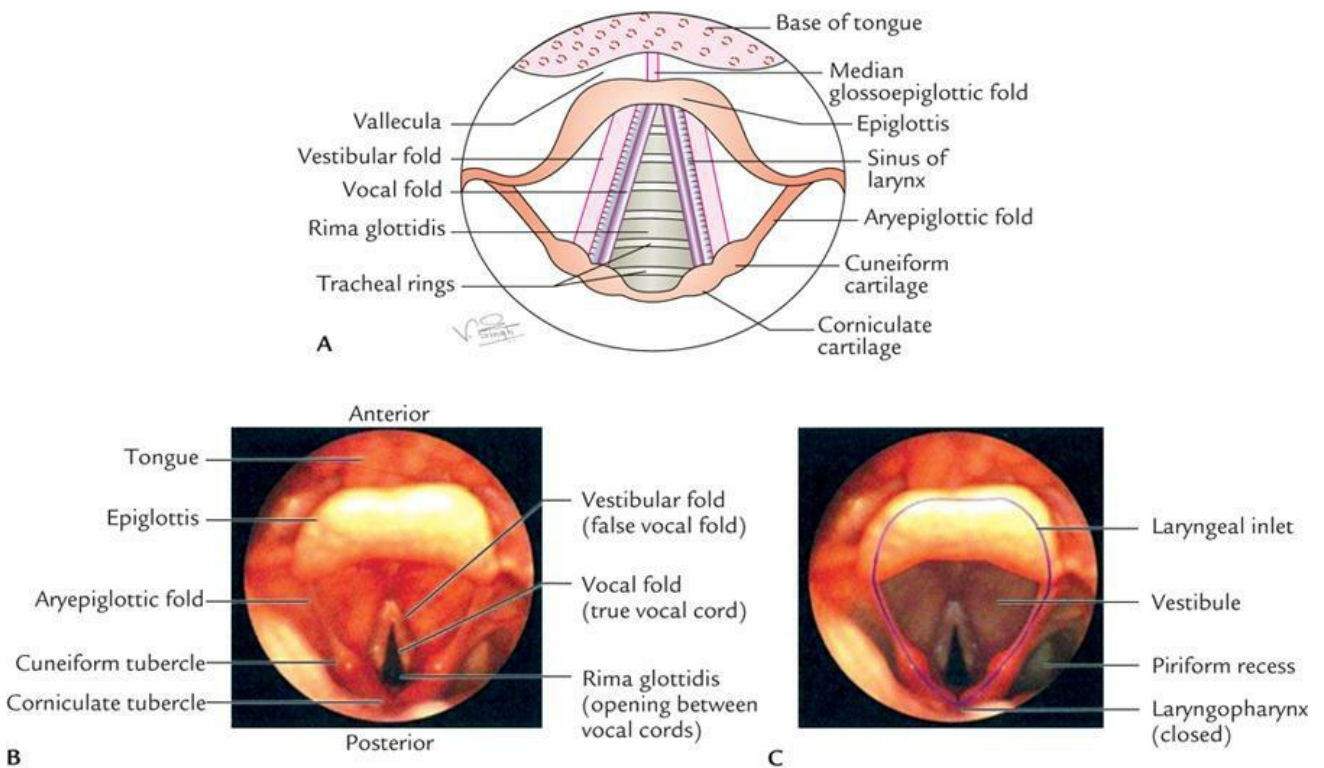

**FIG. 15.13** ■ Vocal nodules.

## CLINICAL CORRELATION

**Laryngoscopy:** The interior of the larynx can be inspected directly by laryngoscope (*direct laryngoscopy*), or indirectly through a laryngeal mirror (*indirect laryngoscopy*). The following structures are viewed (Fig. 15.14):

- Base of tongue
- Valleculae
- Epiglottis
- Aryepiglottic folds
- Piriform fossae
- False vocal cords (red and widely apart)
- True vocal cords (pearly white), medial to false vocal cords
- Sinus of the larynx between false and true vocal cords

**FIG. 15.14 ■** Laryngoscopic view of the laryngeal cavity during moderate respiration. Note that rima glottidis is widely open. ( **A** ) Schematic diagram; ( **B** ) and ( **C** ) actual photographs. ### Golden Facts to Remember

• <b>Largest and most prominent cartilage of the larynx</b>	Thyroid cartilage
• <b>Cartilage, which completely encircles the lumen of larynx</b>	Cricoid cartilage
• <b>Foundation stone of the larynx</b>	
• <b>All the intrinsic muscles of the larynx are paired except</b>	Transverse arytenoid (interarytenoid)

• <b>All the intrinsic muscles of the larynx are adductors of the vocal cords</b>	Posterior cricoarytenoids, which are abductors of the vocal cords
• <b>Opening of larynx (chief tensor of vocal cords)</b>	Cricothyroid
• <b>Modulators of voice</b>	Vocalis muscles
• <b>All the intrinsic muscles of the larynx are supplied by recurrent laryngeal nerve</b>	Cricothyroid, which is supplied by the external laryngeal nerve
• <b>Narrowest region of the laryngeal cavity</b>	Rima glottidis
• <b>Safety muscles of the larynx</b>	Posterior cricoarytenoid
• <b>Singer's nodules</b>	Inflammatory nodules on the vocal cords at the junction of anterior one-third and posterior two-third
• <b>Commonest cancer of the larynx</b>	Squamous cell carcinoma (90%–95%)
• <b>Commonest site of the laryngeal cancer</b>	Glottic region
• <b>Silent area in relation to larynx</b>	Piriform fossa
• <b>Most common congenital abnormality of the larynx</b>	Laryngomalacia (excessive flaccidity of supraglottic portion of larynx)
• <b>Reinke's space</b>	Potential space under the epithelial lining of vocal cord

## CLINICAL CASE STUDY

### Case I

A senior army officer along with his son, daughter, and wife went to a 5-star hotel to have dinner to celebrate the birthday of his wife. The officer consumed three or four shots of alcohol before taking the meal. While having meals, he began to suffocate and collapsed on the floor. The wife who was sitting by his side suspected that probably he has consumed too much alcohol. On close examination, his son who was a final-year MBBS student found that pulse was strong and face began to turn blue (cyanosis). He realized that his daddy was suffering from asphyxia, so he immediately opened his mouth and observed that a piece of meat was caught in the

posterior part of the pharynx. He inserted his index finger and tried to take out the piece of meat. On being unsuccessful, he rolled his daddy into a prone position and with his hands interlocked against the epigastrium and exerted pressure on abdomen two or three times. He was happy that the piece of meat was expelled out. He was diagnosed a case of **cafe coronary phenomenon** .

## Questions

1. Where was the piece of meat most likely lodged?
2. Why are choking and asphyxia common in people who consume alcohol before meals?
3. What is **Heimlich manoeuvre** ?
4. Which is the narrowest part of the laryngeal cavity?

## Answers

1. In the inlet of the larynx, that is, at glottis or supraglottic level.
2. Because of the following two reasons:
  - (a) People who are drunk are less able to chew their food properly and to detect a large bite.
  - (b) In a person who consumes alcohol, the protective explosive cough reflex when a foreign material enters the laryngeal cavity markedly reduces.
3. It is a *first-aid procedure* by which foreign bodies lodged in the respiratory tract are dislodged and expelled out (for details, see page 220, [Fig. 15.9](#) ).
4. Glottis.

## Case II

A 47-year-old man came in the emergency OPD and complained that while eating fish something got stuck in his throat. It was causing pain and lot of discomfort. The physical examination of throat revealed that discomfort increases on moving the thyroid cartilage from side to side. **The physician concluded that the fish bone was stuck in the piriform fossa** .

## Questions

1. What is piriform fossa?
2. What are medial and lateral boundaries of the piriform fossa?

3. What nerve is likely to be injured during the removal of the fish bone?

### Answers

1. Recess in the lateral wall of laryngopharynx, one on either side of laryngeal inlet.
2. Piriform fossa is bounded medially by aryepiglottic fold and quadrangular membrane of the larynx and laterally by inner surface of the thyrohyoid membrane and lamina of thyroid cartilage.
3. Internal laryngeal nerve.

---

# Chapter 16: Blood supply and lymphatic drainage of the head and neck

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe origin, parts, course, and branches of subclavian artery. **AN 35.3**
- Enumerate: (a) branches of first part of subclavian artery, (b) parts of vertebral artery, (c) branches of external carotid artery, and (d) structures passing between external and internal carotid arteries.
- Write short notes on: (a) subclavian artery, (b) styloid apparatus, (c) carotid siphon, and (d) radical neck dissection.
- Give the anatomical basis of: (a) subclavian steal syndrome and (b) subclavian artery pulse.
- Describe origin, course, relations, tributaries, and termination of internal jugular vein. **AN 35.4**
- Describe and demonstrate extent, drainage, and applied anatomy of cervical lymph nodes. **AN 35.5**
- Describe cervical lymph nodes and lymphatic drainage of head, face, and neck. **AN 28.5**

## **Blood supply of head and neck**

The blood supply of head and neck includes both arterial supply and venous drainage. It is carried out by the major blood vessels of head and neck, namely subclavian, vertebral vessels, carotid arteries and internal jugular

veins. The medical students must know the location of larger blood vessels of the head and neck because these vessels may become compromised because of disease process or during surgical procedures. The blood vessels also spread infection to head and neck. Further, they may also spread cancer cells from a malignant tumour to distant sites (*metastasis*) and at a faster rate than lymph vessels. The blood vessels are less numerous than lymph vessels yet the lymph vessels usually run parallel the veins.

## Arterial supply

The arteries that supply the head and neck are subclavian and common carotid arteries (Fig. 16.1). **The main arteries of the head and neck are right and left common carotid arteries**, each of which divides into: (a) an external carotid artery and (b) an internal carotid artery. The external carotid artery supplies structures external to the head and greater part of the neck. The internal carotid artery supplies structures within the cranial cavity and the orbit. The common carotid, external carotid, and internal carotid together form the **carotid system of arteries**. The carotid system of arteries forms the major source of arterial blood supply to the head and neck.

**FIG. 16.1** ■ Arteries supplying the head and neck.

### Subclavian arteries AN 35.3

The subclavian artery is so called because it is located beneath the clavicle. It is an important artery at the root of neck because it not only is the main source of blood supply to the upper limb but also supplies considerable part of the thoracic wall, head, neck, and brain.

#### Origin (Fig. 16.2 )

1. The *right subclavian artery* arises from the brachiocephalic trunk behind the right sternoclavicular joint at the root of neck. Note brachiocephalic trunk arises directly from arch of aorta.
2. The *left subclavian artery* arises directly from the arch of aorta in the thorax. It runs upwards on the left mediastinal pleura and makes groove on the left lung and enters the neck by passing behind the left sternoclavicular joint.

#### N.B.

Based on their origin, the right subclavian artery has only cervical part, whereas the left subclavian artery has thoracic as well as cervical parts. The *cervical part* extends from sternoclavicular joint to the outer border of the 1st rib.

**FIG. 16.2 ■** Origin of the subclavian arteries. Note that the right subclavian artery arises from the brachiocephalic trunk, whereas the left subclavian artery arises directly from the arch of aorta.

**Course (Fig. 16.3 )**

In the neck, both the arteries pursue a similar course.

**FIG. 16.3** ■ Parts of the subclavian artery.

On each side, the subclavian artery arches laterally across the anterior surface of the cervical pleura onto the 1st rib posterior to the scalenus anterior muscle. At the outer border of 1st rib, it ends by becoming axillary artery.

### Termination

At the outer border of 1st rib where the subclavian artery continues as the axillary artery.

### Parts

On each side, subclavian artery is divided into three parts by the scalenus anterior muscle (Fig. 16.3 ). These are as follows:

1. **First part** extends from origin to medial border of scalenus anterior.
2. **Second part** lies behind the scalenus anterior muscle.
3. **Third part** extends from the lateral border of scalenus anterior to the outer border of the 1st rib.

### Relations (Fig. 16.4 )

The relations of the three parts of subclavian artery are as follows.

**FIG. 16.4 ■** Schematic diagram to show the relations of right subclavian artery.

## First part

### *Anterior:*

1. The common carotid artery, internal jugular vein, vagus nerve, vertebral vein, sternocleidomastoid, sternothyroid and sternohyoid muscles.
2. Thoracic duct (only on the left side), cervical cardiac branches of the vagus and sympathetic trunk; and ansa subclavia (encircling the subclavian artery), and phrenic nerve on the left side only.

### *Posterior:*

1. Apex of the lung covered by the cervical pleura and suprapleural membrane.
2. Sympathetic trunk and right recurrent laryngeal nerve, which hooks the undersurface of the right subclavian artery.

## Second part

*Anterior:*

1. Scalenus anterior muscle
2. Phrenic nerve (only on the right side)
3. Sternocleidomastoid.

*Behind:*

1. Apex of lung covered by the cervical pleura and suprapleural membrane
2. Lower trunk of the brachial plexus and scalenus medius muscle.

### Third part

*Anterior:*

1. Suprascapular and transverse cervical vessels
2. Subclavian and external jugular veins
3. Anterior jugular vein

*Behind:*

1. Apex of lung covered by the cervical pleura and suprapleural membrane
2. Lower trunk of the brachial plexus and scalenus medius muscle.

### N.B.

The second part forms the summit of the arch of the subclavian artery and rises 1.5–2.5 cm above the level of the clavicle. It emerges through the gap between scalenus anterior and scalenus medius muscle along with lower trunk of the brachial plexus.

### CLINICAL CORRELATION

**Subclavian artery pulse:** The third part of the subclavian artery is most superficial in the supraclavicular fossa. Here, it lies on the 1st rib. Its pulsations can be felt here by compressing downwards and backwards immediately posterior to the junction medial and middle thirds of clavicle. It is also the **pressure point** of subclavian artery, that is it can be compressed here against the 1st rib by pressing downwards, backwards, and medially in the angle between the clavicle and posterior border of the sternocleidomastoid muscle. It can also be ligated conventionally at this site (Fig. 16.5). The blood supply to the upper limb is not hampered because of adequate collateral circulation.

**FIG. 16.5 ■** Subclavian artery pulse.

### Branches of the subclavian artery (Fig. 16.6 )

The subclavian artery usually gives off four branches. All of them arise from first part with the exception of costocervical trunk, which on the right side arises from the second part.

- *From the first part: three branches*
  1. Vertebral artery
  2. Thyrocervical trunk
    - a) Inferior thyroid artery
    - b) Transverse cervical artery
    - c) Suprascapular artery
  3. Internal thoracic artery
- *From the second part: one branch*
  - **Costocervical trunk** (only on the right side)
- *From the third part: one branch*
  - **Dorsal scapular artery** : It is an occasional branch that may arise from the third part of the subclavian artery. When present, it replaces the deep branch of the transverse cervical artery.

**FIG. 16.6 ■** Branches of the right and left subclavian arteries.

### **N.B.**

Costocervical trunk (on left side arises from first part).

### **Vertebral artery**

The paired vertebral arteries are one of the principal arteries, which supplies the brain and upper part of spinal cord.

Each vertebral artery is the first and largest branch of the first part of the subclavian artery (Fig. 16.7).

**FIG. 16.7** ■ Course and parts of the vertebral artery.

### Origin, course, and termination

The vertebral artery arises from the upper aspect of the first part of the subclavian artery, runs vertically upwards to enter the foramen transversarium of the transverse process of C6. Then it passes through foramina transversaria of the upper six cervical vertebrae.

After emerging from the foramen transversarium of C1, it winds backwards

around the lateral mass of the atlas passes behind the superior articular process and reaches the groove on the superior surface of the posterior arch of atlas. From here it passes under posterior atlanto-occipital membrane and enters the cranial cavity through foramen magnum (see [Figs 7.9](#) and [7.10](#) ).

In the cranial cavity, it unites with the vertebral artery of the opposite side at the lower border of the pons to form the **basilar artery** .

### Parts ([Fig. 16.7](#) )

The vertebral artery is divided into four parts, namely

1. **First (cervical) part** extends from origin to foramen transversarium of C6 vertebra. This part lies in the *scalenovertbral triangle* .
2. **Second (vertebral) part** lies within the foramina transversaria of upper six cervical vertebrae.
3. **Third (suboccipital) part** extends from foramen transversarium of C1 vertebra to the foramen magnum of skull. This part lies horizontally within the suboccipital triangle.
4. **Fourth (intracranial) part** extends from foramen magnum to the lower border of the pons. Where it joins with its fellow of opposite side to form basilar artery ([Fig. 16.7](#) ).

### Branches

#### ***In the neck (cervical branches)***

1. **Spinal branches** : They arise from the second (vertebral) part and enter the vertebral canal through intervertebral foramina to supply the upper five or six cervical segments of the spinal cord.
2. **Muscular branches** : They arise from the first and third parts of the vertebral artery. Those from the first part, supply deep muscles of the neck and those from the third part, supply the muscles of the suboccipital triangle.

#### ***In the cranial cavity (cranial branches)***

- They arise from the fourth part. These are as follows:
  1. Meningeal branches
  2. Posterior spinal artery
  3. Anterior spinal artery
  4. Posterior inferior cerebellar artery
  5. Medullary branches.

- **Vertebral artery rotational syndrome/ vertebro-basilar syndrome.** The vertebral artery after emerging from foramen transversarium of atlas, turns medially and posteriorly behind the superior articular process of atlas to lie in the groove on the superior surface of arch of atlas. From here it passes deep to posterior atlanto-occipital membrane. Therefore it is susceptible to compression and occlusion due to rotation of head. The compression of vertebral artery will lead to transient ischaemic attacks, syncope, dizziness, etc.

**Subclavian steal syndrome ( Fig. 16.8 ):** If there is an obstruction of the subclavian artery proximal to the origin of vertebral artery, some amount of blood from opposite vertebral artery will pass in a retrograde fashion to the subclavian artery of the affected side through the vertebral artery of that side to provide the collateral circulation to the upper limb on the side of lesion. Thus, there occurs a sort of stealing of blood to brain by the subclavian artery of the affected side. Hence, the name *subclavian steal syndrome*.

## FIG. 16.8 ■ Subclavian steal syndrome.

### Internal thoracic artery (internal mammary artery)

The internal mammary artery arises from the inferior aspect of the first part of the subclavian artery opposite the origin of thyrocervical trunk. It passes downwards and medially in front of the cupola of the cervical pleura and enters the thorax behind the sternoclavicular joint.

In the thorax, it passes vertically downwards, approximately 1.25 cm away from the lateral border of the sternum, up to the level of the 6th intercostal space, where it divides into two terminal branches: **musculophrenic** and **superior epigastric arteries** (for details, see *Textbook of Anatomy: Upper Limb and Thorax*, Vol. I, 4ed. by Vishram Singh).

### Thyrocervical trunk

It is the short, wide branch of the subclavian artery.

### Origin, course, and termination

The thyrocervical trunk arises from upper aspect of the first part of the subclavian artery at the medial margin of the scalenus anterior and lateral to the origin of vertebral artery. It immediately terminates into three branches.

### Branches (Fig. 16.6 )

These are as follows:

1. Inferior thyroid artery
2. Transverse cervical artery
3. Suprascapular artery.

### Inferior thyroid artery

It ascends along the medial border of scalenus anterior and just below transverse process of C6 vertebra, it turns medially in front of the vertebral artery and posterior to vagus nerve, sympathetic trunk and common carotid artery to reach the posterior surface of the lateral lobe of the thyroid gland. Then it descends to the lower pole of the thyroid lobe and divides into **ascending** and **descending glandular branches** .

*Other small branches:*

In addition to glandular branches to thyroid gland, it also gives the following branches:

1. **Ascending cervical artery** passes upwards in front of the transverse processes of cervical vertebrae along the medial side of the phrenic nerve and acts as a guide to this nerve. It supplies prevertebral muscles and sends spinal branches to the vertebral canal along the spinal nerves.
2. **Inferior laryngeal artery** accompanies the recurrent laryngeal nerve to the larynx and supplies the mucous membrane of the larynx below the vocal cord and muscles of the larynx.
3. **Tracheal, pharyngeal, and oesophageal branches** to trachea, pharynx, and oesophagus, respectively.

### Transverse cervical artery

It passes laterally and upwards across the scalenus anterior to reach the posterior triangle, where it lies in front of the trunks of the brachial plexus. Here, it further divides into superficial and deep branches. The superficial branches ascend beneath the trapezius and anastomoses with the superficial division of the descending branch of the occipital artery.

The deep branch courses deep to the levator scapulae and takes part in the scapular anastomosis.

### Suprascapular artery

It passes laterally across the scalenus anterior to lie in front of the third part of the subclavian artery and brachial plexus. Now it passes behind the clavicle to reach the suprascapular notch of the scapula, where it passes above the suprascapular ligament to enter the suprascapular fossa and takes part in the formation of **arterial anastomosis around the scapula** .

### Costocervical trunk (Fig. 16.9 )

#### Origin

It arises from posterior aspects of: (a) **first part of the subclavian artery on the left side** and (b) **second part of the subclavian artery on the right side** .

**FIG. 16.9 ■** Schematic diagram showing origin, course, and branches of the costocervical trunk.

### Course and termination

The artery arches backwards above the cupola of the pleura, and on reaching the neck of the 1st rib, it terminates by dividing into ascending deep cervical artery and descending superior (highest) intercostal artery.

**Deep cervical artery** passes backwards between the transverse process of C7 vertebra and neck of the 1st rib. It then ascends between the semispinalis capitis and semispinalis cervicis and anastomoses with the deep division of the descending branch of the occipital artery.

**Superior (highest) intercostal artery** descends in front of the neck of the first two ribs and gives rise to posterior intercostal arteries to the first two intercostal spaces.

### Dorsal scapular artery

It arises from the third part of the subclavian artery (but may be the deep branch of the transverse cervical artery). As a direct branch of the subclavian artery, it passes laterally and backwards between the trunks of brachial plexus to reach underneath the levator scapulae. Now it descends along the medial border of the scapula in company with dorsal scapular nerve deep to rhomboids and takes part in the formation of **arterial anastomosis around the scapula**.

The branches of subclavian artery and their subsequent branches are

summarized in [Table 16.1](#) .

 **TABLE 16.1**

### Summary of branches of the subclavian artery and their subsequent branches

Branches	Subsequent branches
<b><i>Vertebral artery</i></b>	
• First (cervical) part	Muscular branches
• Second (vertebral) part	Spinal branches
• Third (suboccipital) part	Muscular branches
• Fourth (intracranial) part	Meningeal branches Posterior spinal artery Posterior inferior cerebellar artery Medullary branches
<b><i>Internal thoracic artery</i></b>	(See <i>Textbook of Anatomy : Upper Limb and Thorax</i> , Vol. I, 4ed. by Vishram Singh)
<b><i>Thyrocervical trunk</i></b>	
• Inferior thyroid artery	Glandular branches Ascending cervical artery Inferior laryngeal artery Tracheal, pharyngeal, and oesophageal branches
• Suprascapular artery	(See <i>Textbook of Anatomy: Upper Limb and Thorax</i> , Vol. I, 4ed. by Vishram Singh)
• Transverse cervical artery	Superficial branch Deep branch/dorsal scapular artery
<b><i>Costocervical trunk</i></b>	Deep cervical artery Superior intercostal artery

## CLINICAL CORRELATION

- **Cervical rib** may compress the subclavian artery as it passes through the gap between the scalenus anterior and scalenus medius muscles. This can be tested clinically when the patient's chin is turned upwards and to the affected side after a deep breath the radial pulse is diminished or obliterated (*Adson's test*) .
- **Aneurysm** may develop in the third part of subclavian artery. The pressure due to aneurysm on the brachial plexus causes numbness, weakness, and pain in the upper limb.
- **Dysphagia lusoria:** The right subclavian artery sometimes may arise from descending thoracic aorta and compress oesophagus leading to difficulty in swallowing. This condition is called *dysphagia lusoria* .

### Common carotid arteries AN 35.9

There are two common carotid arteries: right and left. They are the chief arteries of the head and neck.

#### Origin (Fig. 16.1 )

The **right common carotid artery** arises in neck from *brachiocephalic trunk* (innominate artery) behind the sternoclavicular joint.

The **left common carotid artery** arises in thorax (superior mediastinum) directly from the *arch of aorta* . It ascends to the back of left sternoclavicular joint and enters the neck.

#### Course, termination, and relations

In the neck, both arteries (right and left) have similar course. Each artery runs upwards from sternoclavicular joint to the upper border of the lamina of thyroid cartilage (opposite the disc between the 3rd and 4th cervical vertebrae), where it terminates by dividing into internal and external carotid arteries. The internal carotid artery is considered as a continuation of common carotid artery. They are named as internal and external because the former supplies structures within the skull and latter supplies structures outside the skull.

Each common carotid artery lies in front of transverse processes of lower four cervical vertebrae under cover of anterior border of the

sternocleidomastoid muscle.

### Branches

The common carotid artery gives only two terminal branches, that is external and internal carotid arteries.

### CLINICAL CORRELATION

- **Compression of common carotid artery (see page 91).**
- **Carotid pulse (see page 91).**

### External carotid artery (Fig. 16.10 )

It is one of the two terminal branches of the common carotid artery and supplies the structures external to the head and in front of the neck.

**FIG. 16.10 ■** Curved course of the external carotid artery. Note the relationship of the external carotid with the internal carotid arteries.

### **Course and relations**

The external carotid artery extends upwards from the level of upper border of the lamina of the thyroid cartilage to a point behind the neck of the mandible, where it terminates in the substance of the parotid gland by dividing into the superficial temporal and maxillary arteries.

The external carotid artery has a slightly curved course so that it is anteromedial to the internal carotid artery in its lower part and anterolateral to the internal carotid artery in its upper part ([Fig. 16.10](#) ).

### **Branches ([Fig. 16.11](#) )**

The external carotid artery gives rise to eight branches as follows:

1. **S**uperior thyroid artery
2. **L**ingual artery
3. **P**osterior auricular artery
4. **F**acial artery
5. **O**ccipital artery
6. **A**scending pharyngeal artery
7. **M**axillary artery
8. **S**uperficial temporal artery

**FIG. 16.11** ■ Branches of the external carotid artery.

**Mnemonic** – **S**ister **L**ucy's **P**retty **F**ace **O**ften **A**ttracts **M**edical **S**tudents.

The first three arteries arise from anterior aspect, next two from posterior aspect, and next one from medial aspect. The last two arteries are terminal branches.

The branches of the external carotid artery are eight in number. This number corresponds to number of letters in the term EXTERNAL which also consists of 8 letters.

1. **Superior thyroid artery:** It arises from the front of external carotid

artery just below the tip of the greater cornu of the hyoid bone. It runs downwards and forwards, parallel and superficial to the external laryngeal nerve to reach the upper pole of the thyroid gland, which it supplies.

◦ **Branches** (Fig. 16.12 )

- (a) *Infrathyoid branch* , which anastomoses with its fellow of opposite side.
- (b) *Sternomastoid branch* to the sternomastoid muscle.
- (c) *Superior laryngeal artery* accompanies the internal laryngeal nerve, passes deep to the thyrohyoid muscle and pierces the thyrohyoid membrane to supply the larynx.
- (d) *Cricothyroid branch* passes across the cricothyroid ligament and anastomoses with its counterpart of the opposite side.
- (e) *Glandular branches* to the thyroid gland; one of which anastomoses with its fellow of the opposite side along the upper border of the isthmus of the thyroid gland.

2. **Lingual artery:** It arises from the front of the external carotid artery opposite the tip of the greater cornu of the hyoid bone. It is the main artery to supply blood to the tongue. It may arise in common with the facial artery (*linguofacial trunk*) .

◦ It is divided into three parts by the hyoglossus muscle, namely (see Chapter 13 , page 188)

- (a) *First part* lies in the carotid triangle and forms a characteristic loop with convexity upwards above the greater cornu. The loop is crossed superficially by the hypoglossal nerve. The loop permits free movement of the hyoid bone.
- (b) *Second part* lies deep to the hyoglossus muscle along the upper border of the hyoid bone.
- (c) *Third part* (also called *arteria profunda linguae* ) or *deep lingual artery* first runs upwards along the anterior border of the hyoglossus muscle and then forwards on the undersurface of the tongue, where it anastomoses with its fellow of opposite side.

◦ **Branches**

- (a) *From first part – suprahyoid branch* . It anastomoses with its fellow of opposite side.
- (b) *From second part – dorsal linguae branches* usually two in number, to the dorsum of tongue and tonsil.

(c) *From third part – sublingual artery* , to the sublingual gland.

3. **Facial artery (formerly called external maxillary artery):** It arises from the front of the external carotid artery just above the tip of the greater cornu of the hyoid bone.

◦It is divided into two parts – cervical and facial:

(a) *Cervical part* of the facial artery ascends deep to the digastric and stylohyoid muscles, passes deep to the ramus of mandible where it grooves the posterior border of the submandibular gland. Then it makes S-shaped bend, first bending down (with convexity upwards) over the submandibular gland and then up (with convexity downwards) over the base of the mandible.

(b) *Facial part* of the facial artery begins where the facial artery winds around the lower border of the body of the mandible at the anteroinferior angle of the masseter. (It has already been described in [Chapter 3](#) .)

◦**Branches**

◦**From the cervical part** (branches in the neck)

(a) *Ascending palatine artery* arises near the origin of facial artery, ascends, and accompanies the levator palati, passes over the upper border of the superior constrictor and supplies mainly the palate.

(b) *Tonsillar artery* (main artery of tonsil) pierces the superior constrictor and ends in the tonsil.

(c) *Glandular branches* supply the submandibular gland.

(d) *Submental artery* , a large artery, which runs forwards on the mylohyoid muscle in company with mylohyoid nerve. It supplies the mylohyoid muscle and submandibular and sublingual salivary glands.

◦**From the facial part** (see [Chapter 3](#) , page 60)

4. **Occipital artery:** It arises from the posterior aspect of the external carotid artery at the same level as that of facial artery. It runs backwards and upwards under cover of lower border of the posterior belly of digastric muscle superficial to internal carotid artery, internal jugular vein, and last four cranial nerves.

◦Then it runs deep to the mastoid process grooving the lower surface of the temporal bone medial to the mastoid notch. Then it crosses

the apex of the posterior triangle. It crosses the superior oblique and semispinalis capitis and apex of suboccipital triangle to reach underneath the trapezius muscle, which it pierces 2.5 cm away from the midline and comes to lie just lateral to the **greater occipital nerve** . It supplies most of the back of the scalp.

◦**Branches**

- (a) *Sternomastoid branches* are usually two in number and arise in the carotid triangle. They run downwards and backwards, and supply the sternocleidomastoid. The upper one accompanies the spinal accessory nerve and lower one is hooked by the hypoglossal nerve.
- (b) *Mastoid branch* enters the cranial cavity through mastoid foramen and supplies mastoid air cells.
- (c) *Meningeal branches* enter the cranial cavity through jugular foramen and hypoglossal canal to supply dura mater of posterior cranial fossa.
- (d) *Muscular branches* supply adjoining muscles.
- (e) *Auricular branch* (occasional) supplies the cranial surface of the auricle.
- (f) *Descending branch* divides into superficial and deep branches. The superficial branch anastomoses with the superficial branch of transverse cervical artery and deep branch anastomoses with the deep cervical artery – a branch of the costocervical trunk of subclavian artery on the superficial and deep surfaces of the semispinalis capitis, respectively.

**FIG. 16.12** ■ Distribution of the branches of the external carotid artery (shown in *dark red* ). AP, ascending palatine artery; F, facial artery; L, lingual artery; OC, occipital artery; PA, posterior auricular artery.

### N.B.

The descending branch of the occipital artery provides the chief collateral circulation after ligation of the external carotid or the subclavian artery (vide supra).

### N.B.

- The *hypoglossal nerve* hooks the occipital artery under its site of origin.
- The *upper sternomastoid branch* of occipital artery accompanies the

spinal accessory nerve and the lower sternomastoid branch crosses the hypoglossal nerve.

- The *occipital artery* crosses the apical part of the posterior triangle.

5. **Posterior auricular artery:** It arises from the posterior aspect of the external carotid artery a little above the occipital artery. It crosses superficial to the stylohyoid muscle. It runs upwards and backwards parallel to the occipital artery along the upper border of the posterior belly of digastric muscle and deep to the parotid gland. Then it becomes superficial and lies on the base of mastoid process behind the ear, which it supplies.

◦**Branches**

- (a) *Stylomastoid artery* enters the stylomastoid foramen to supply middle ear, mastoid air cells, and facial nerve.
- (b) *Auricular branch* supplies both cranial and lateral surfaces of the auricle.
- (c) *Occipital branch* supplies scalp above and behind the auricle.

**N.B.**

The posterior auricular artery is cut in incisions for mastoid operations.

6. **Ascending pharyngeal artery:** It is a slender artery that arises from the medial aspect of the external carotid artery near its lower end. It runs vertically upwards between the side wall of the pharynx and internal carotid artery up to the base of the skull.

◦**Branches**

- (a) Pharyngeal and prevertebral branches to corresponding muscles
- (b) *Meningeal branches*, which traverse foramina in the base of the skull
- (c) *Inferior tympanic*, which supplies medial wall of tympanic cavity
- (d) *Palatine branches*, which accompany levator veli palatini to the palate.

7. **Superficial temporal artery:** It is the smaller but more direct terminal branch of the external carotid artery. It begins behind the neck of the mandible deep to the upper part of the parotid gland. It runs vertically upwards crossing the root of zygoma in front of the tragus where its pulsation can be felt.

◦ Approximately 5 cm above the zygoma, it divides into anterior and posterior branches, which supply the temple and scalp.

◦ **Branches**

(a) *Transverse facial artery* runs forwards across the masseter below the zygomatic arch.

(b) *Anterior auricular branch* supplies the lateral surface of auricle and external auditory meatus.

(c) *Zygomatico-orbital artery* runs forwards along the upper border of zygomatic arch between two layers of temporal fascia and reaches the lateral angle of the eye.

(d) *Middle (deep) temporal artery* runs on the temporal fossa deep to temporalis muscle and supplies temporalis muscle and fascia.

(e) *Anterior (frontal) and posterior (parietal) terminal branches.*

The *anterior terminal branch* runs forwards towards frontal tuberosity and supplies the muscles and skin of the frontal region. It is very tortuous and anastomoses with the branches of the ophthalmic artery. The tortuosity of this artery is often seen in old age.

The larger *posterior terminal branch* runs upwards and backwards to reach the occipital region where it supplies skin and the auricular muscles.

## CLINICAL CORRELATION

- **Superficial temporal pulse:** The pulsations of superficial temporal artery can be readily felt in front of the tragus of the ear (*where it crosses the root of zygoma, the preauricular point*). It serves the useful purpose to anaesthetists to whom the radial pulse is not available during surgery. For this reason, it is also called **anaesthetist's artery**.

## N.B.

The course of anterior terminal branch of the superficial temporal artery on the forehead can clearly be seen in a bald angry man. It becomes noticeably more tortuous with increasing age.

**8. Maxillary artery:** It is the larger terminal branch of the external

carotid artery (see [Chapter 10](#) , pages 134–137).

## **Internal carotid artery**

The internal carotid artery is one of the two terminal branches of the common carotid artery but it is more direct. It is considered as an upward continuation of the common carotid artery. *It supplies structures inside the skull and in the orbit. It is the principal artery to supply the brain and eye .*

It begins as the upper border of the lamina of thyroid cartilage at the level of the disc between C3 and C4 vertebrae and runs upwards to reach the base of the skull, where it enters the carotid canal in the petrous temporal bone. It emerges in the cranial cavity by passing through the upper part of the foramen lacerum. In the cranial cavity, it enters the cavernous sinus and pursues a tortuous course before it ends below the anterior perforated substance of the brain by dividing into the *anterior* and *middle cerebral arteries*.

## **Parts**

For the sake of convenience, the course of the internal carotid artery is divided into the following four parts:

1. **Cervical part:** It ascends vertically upwards from its origin to the base of the skull to reach the lower end of carotid canal and lies on the front of transverse process of upper cervical vertebrae. In the neck, the internal carotid artery is enclosed in the carotid sheath along with the internal jugular vein and vagus nerve.
  - The lower part of the artery is superficial and located in the carotid triangle. The upper part is deeply located and lies deep to the posterior belly of digastric muscle, styloid process with structures attached to it and parotid gland.
  - At the upper end, the internal jugular vein lies posterior to the internal carotid artery. Here the last four cranial nerves (glossopharyngeal, vagus, accessory, and hypoglossal) lie between the internal jugular vein and internal carotid artery.
- Branches**
  - In the neck, the internal carotid artery gives no branches.
2. **Petrous part:** The internal carotid artery enters the petrous part of the temporal bone in carotid canal. It first runs upwards and then turns forwards and medially at the right angle. It emerges at the apex

of petrous temporal bone in the posterior wall of foramen lacerum, and passes through its upper part to enter the cranial cavity.

◦**Branches**

- (a) *Caroticotympanic branches* to middle ear, which anastomose with the anterior and posterior tympanic arteries.
- (b) *Pterygoid branch (small and inconstant)* enters the pterygoid canal and anastomoses with the greater palatine artery.

3. **Cavernous part:** This part lies within the cavernous sinus. From foramen lacerum, the internal carotid artery ascends and enters the cavernous sinus. In the sinus, it passes forwards along the side of sella turcica in the floor and medial wall of the sinus. Here, it lies outside the endothelial lining of the sinus and related to the abducent nerve inferolaterally.

- In the anterior part of the sinus, the artery ascends and pierces the dural roof of the sinus between the anterior and middle clinoid processes to reach underneath the cerebrum.

◦**Branches**

- (a) *Cavernous branches* to the trigeminal ganglion.
- (b) *Superior and inferior hypophyseal arteries* to the hypophysis cerebri (pituitary gland).

4. **Cerebral part:** This part lies at the base of the brain. After emerging from the roof of the cavernous sinus, the artery turns backwards in the subarachnoid space along the roof of the cavernous sinus and lies below the optic nerve.

- Finally, it turns upwards by the side of the optic chiasma and reaches the anterior perforated substance of the brain located at the beginning of the stem of lateral sulcus of the cerebral hemisphere. Here it ends by dividing into anterior and middle cerebral arteries.

◦**Branches**

The branches of cerebral part of the internal carotid artery are described in detail in [Chapter 29](#) , page 396. The branches of internal carotid artery are summarized in [Table 16.2](#) .

## Summary of branches of the internal carotid artery

Parts	Branches	
Cervical part	No branches	
Petrous part	<ol style="list-style-type: none"><li>1. Caroticotympanic branches</li><li>2. Pterygoid branch</li></ol>	
Cavernous part	<ol style="list-style-type: none"><li>1. Cavernous branches</li><li>2. Superior and inferior hypophyseal arteries</li></ol>	
Cerebral part	<ol style="list-style-type: none"><li>1. Ophthalmic artery</li><li>2. Anterior choroidal artery</li><li>3. Posterior communicating artery</li><li>4. Anterior cerebral artery</li><li>5. Middle cerebral artery</li></ol>	Terminal branches

### N.B.

**Carotid siphon:** The U-shaped bend formed by the internal carotid artery while passing through and above the cavernous sinus is called *carotid siphon*. It probably dampens down the pulsations of the artery. The carotid siphon is an important feature to be seen in cerebral angiography.

### CLINICAL CORRELATION

**Elective arterial surgery of carotid vessels:** The carotid vessels are exposed during elective arterial surgery for aneurysms, arteriovenous fistulae, or arteriosclerotic occlusion. It is now established that *partial or complete obstruction due to arteriosclerosis is a common cause of cerebral stroke*. In fact, it may account for 20% of the cerebrovascular accidents, which at one time were believed to be due to either intracranial haemorrhage or thrombosis.

**Carotid end arterectomy:** Removal of atherosclerotic plaque with intima of carotid artery is done to relieve the symptoms.

The **structures passing between the external and internal carotid arteries** are as follows (Fig. 16.13 ):

**FIG. 16.13** ■ Structures passing between the internal and external carotid arteries.

1. Styloid process
2. Deep part of the parotid gland
3. Styloglossus muscle
4. Stylopharyngeus muscle
5. Glossopharyngeal nerve
6. Pharyngeal branch of the vagus nerve.

## Veins

The major veins draining the head and neck are subclavian, internal jugular,

external jugular, and anterior jugular veins (Fig. 16.14 ). The *internal jugular vein* is the principal vein of the head and neck region, for it drains the brain as well as most of other tissues of the head and neck. The external jugular vein drains only a portion of extracranial tissues.

**FIG. 16.14** ■ Great blood vessels at the root of the neck.

The valves in the lumen are mostly absent in the veins draining head and neck area, unlike in the rest of the body. This leads to two-way flow of blood dictated by local pressure changes. For this reason, infections in the head and neck area can lead to serious complications.

### **Subclavian vein**

It is the continuation of axillary vein and extends from outer border of the 1st rib to the medial border of the scalenus anterior, where it joins the internal jugular vein to form brachiocephalic vein (Fig. 16.14 ). The *subclavian vein* is

*principally the vein of the upper limb.*

The subclavian vein forms an arch across the pleura at a level below the arch of the subclavian artery. The two arches are separated from each other by the scalenus anterior.

It seldom rises above the level of the clavicle and possesses a pair of valves approximately 2 cm from its termination.

### **Relations (Fig. 16.15 )**

*In front:* Clavicle and subclavius muscle

*Behind:* Subclavian artery with intervening scalenus anterior muscle and phrenic nerve

*Below:* 1st rib and cupola of pleura.

### **Tributaries**

The following are the tributaries of the subclavian vein:

**FIG. 16.15 ■** Relations of the subclavian vein.

1. External jugular vein. 2. Dorsal scapular vein. 3. Thoracic duct on the left side and right lymphatic duct on the right side.	
4. Anterior jugular vein. 5. Cephalic vein.	Only sometimes

## CLINICAL CORRELATION

- Subclavian vein catheterization:** The subclavian vein is located immediately posterior to the medial third of the clavicle. It can be catheterized both from below (*infraclavicular approach*) and above (*supraclavicular approach*) the clavicle.
  - In *infraclavicular approach*, the needle is inserted just below the lower border of the clavicle at the junction of its medial one-third and lateral two-third. The needle is directed upwards and posteriorly towards the middle of the jugular notch.
  - In *supraclavicular approach*, the needle is inserted at the junction of lateral border of the clavicular head of sternocleidomastoid and upper border of the clavicle. The needle is directed downwards and medially towards the mediastinum.
- Subclavian vein thrombosis:** It can be spontaneous (primary) or secondary. Clinically, it presents as oedema of the upper limb especially after exercise. The *primary thrombosis* occasionally occurs because of excessive and unaccustomed use of arm at the shoulder joint. The *secondary thrombosis* occurs as a complication of an indwelling venous catheter.

## Internal jugular vein AN 35.4

The internal jugular vein is usually the largest vein in the neck. It begins as the direct continuation of the sigmoid sinus at the base of the skull below the jugular foramen and descends vertically downwards to end behind the sternal end of the clavicle by joining the subclavian vein to form the brachiocephalic

vein. The internal jugular vein drains brain and most of the tissues of the head and neck (Fig. 16.16 ).

**FIG. 16.16** ■ Beginning and termination of the internal jugular veins along with their tributaries.

**N.B.**

The right internal jugular vein is usually larger than the left because it drains blood from the larger superior sagittal sinus, cf. the left internal jugular vein drains blood from the smaller inferior sagittal sinus.

## Special features

1. It presents two dilatations:
  - First, at its commencement, which lies in the jugular fossa of the temporal bone, it is known as **superior bulb** and is related to the floor of the middle ear.
  - Second, close to its termination, which lies in the lesser supraclavicular fossa between the sternal and clavicular heads of sternocleidomastoid, it is known as **inferior bulb** and is guarded by a pair of valves.
2. It is vertically applied to the lateral side of the internal and common carotid arteries, enclosed with them and the vagus nerve in the fascial sheath called **carotid sheath**.
3. The deep cervical lymph nodes lie along its entire course.
4. It is remarkably constant in position and can be marked on the surface by a vertical line extending from midpoint between the tip of the mastoid process and the angle of the mandible, to the sternoclavicular joint.

### N.B.

At the lower end, both the internal jugular veins (right and left) tend to shift to the right, so that the right comes to lie further lateral to the right common carotid artery while the left tends to overlap the left common carotid artery.

## Relations

### Deep (posterior):

◦From above downwards, these are ([Fig. 16.17](#)) as follows:

1. Rectus capitis lateralis
2. Transverse process of atlas
3. Levator scapulae
4. Scalenus medius and cervical plexus
5. Scalenus anterior and phrenic nerve
6. Thyrocervical trunk and first part of vertebral artery
7. First part of the subclavian artery
8. Thoracic duct on the left side.

### Superficial (anterolateral; [Fig. 16.18](#)):

◦These are as follows:

- Overlapped by one muscle: sternocleidomastoid

- 2. Crossed by two muscles
  - (a) Posterior belly of digastric muscle in the upper part
  - (b) Superior belly of omohyoid in the lower part
- 3. Crossed by two arteries
  - (a) Occipital artery
  - (b) Posterior auricular artery
- 4. **Crossed by one vein** : anterior jugular vein
- 5. *Crossed by two nerves*:
  - (a) Spinal accessory nerve
  - (b) Inferior root of ansa cervicalis (descendens cervicalis)

*Medial:*

- Medially, the vein is related to:
  1. Internal carotid artery and 9th, 10th, 11th, and 12th cranial nerves in the upper part
  2. Common carotid artery and vagus nerve in the lower part (see [Fig. 16.19](#) ).

**Structures forming posterior relations of internal jugular vein**

Internal jugular vein

**FIG. 16.17 ■** Deep (posterior) relations of the internal jugular vein.

**FIG. 16.18** ■ Superficial (anterolateral) relations of the internal jugular vein.

### **Tributaries (Fig. 16.16 )**

1. Inferior petrosal vein is usually the **first tributary** and joins the internal jugular vein immediately below the jugular foramen
2. Pharyngeal veins from pharyngeal plexus

3. Common facial vein
4. Lingual vein
5. Superior thyroid vein
6. Middle thyroid vein
7. Occipital vein (only sometimes).

In addition to the aforementioned tributaries, the **right lymphatic duct** on the right side and **thoracic duct** on the left side usually open into internal jugular vein or into the junction between the internal jugular vein and the subclavian vein.

### N.B.

In the upper part of the neck, internal jugular vein may communicate with the external jugular vein by an *oblique jugular vein* across the anterior border of sternocleidomastoid muscle.

### CLINICAL CORRELATION

- **Internal jugular vein:** This acts as a guide for surgeons during removal of deep cervical lymph nodes. The facial (or common facial) vein is most important tributary of the internal jugular vein, for it serves as a useful landmark in removal of the jugulodigastric (tonsillar) and upper anterior group of deep cervical lymph nodes.
- **Malignant and tuberculous lymph nodes:** These often get adhered to the internal jugular vein and not uncommonly the surgeon has to resect a portion of the vessel in order to facilitate their removal.
- **Internal jugular pulse:** Sometimes a thrill is felt in the internal jugular vein at the root of the neck (in lesser supraclavicular fossa) during contraction of atria in systole, particularly in case of mitral stenosis.
- **Cannulation of internal jugular vein:** The internal jugular vein is safely cannulated by inserting a needle at the apex of the lesser supraclavicular fossa.  
The needle is directed inferiorly towards the ipsilateral nipple, to avoid the puncture of cervical pleura, which, if punctured, will lead to pneumothorax.
- **Right internal jugular vein:** This is preferred to that of left internal jugular vein, for cannulation because it runs a straighter and more direct

course to the right atrium than does the left.

The **anterior jugular** and **external jugular veins** are described in detail in [Chapter 4](#) .

## **Carotid sheath**

The carotid sheath extends from the base of the skull above to the arch of the aorta below. At the upper end, it is attached to the margins of carotid canal and the jugular fossa.

The upper part of the carotid sheath contains internal carotid artery, internal jugular vein, and last four cranial nerves ([Fig. 16.19](#) ). Medial to it lies pharynx, lateral to it lies styloid apparatus, anterior to it lies infratemporal fossa, and posterior to it lies cervical sympathetic trunk on the prevertebral fascia.

**FIG. 16.19** ■ Carotid arteries and nerves associated with them in the neck.

The lower part of carotid sheath contains common carotid artery, internal jugular vein, and vagus nerve.

Also see [Chapter 4](#) ; [Fig. 4.14](#).

## Styloid apparatus

The styloid apparatus consists of styloid process and structures attached to it.

The structures attached to styloid process ([Fig. 16.20](#) ) are as follows:

1. **Three muscles:** Stylohyoid, styloglossus, and stylopharyngeus
2. **Two ligaments:** Stylohyoid and stylomandibular.

### N.B.

The five elongated structures attached to styloid process resemble the **reins of a chariot**. Two of these reins (ligaments) are nonadjustable, whereas the remaining three reins (muscles) are adjustable, with each being controlled by separate cranial nerve; for example, stylohyoid, stylopharyngeus, and styloglossus are supplied by 7th, 9th, and 12th cranial nerves, respectively.

**FIG. 16.20 ■ Styloid apparatus.**

### Styloid process

The styloid process is long, slender, pointed bony process projecting anteroinferiorly from the inferior aspect of the temporal bone. Its length is variable, ranging from 2 and 3 mm to an average of 2.5 cm.

Its proximal part ( **tympanohyal** ) is ensheathed by the tympanic plate, whereas its muscles and ligaments are attached to its distal part ( **stylohyal** ).

Its relations in vivo are important. They are:

1. It projects between external and internal carotid arteries.

2. It is interposed between the parotid gland laterally and internal jugular vein medially.
3. Laterally, facial nerve crosses its base and external carotid artery crosses its apex.

## **Muscles attached to styloid process**

### **Stylohyoid muscle**

It is a slender muscle extending from posterior surface of the styloid process to the hyoid bone at the junction between its body and greater cornu (for details, see [Chapter 9](#) ). It helps in controlling movements of the hyoid bone.

### **Styloglossus muscle**

It extends from anterior surface of the tip of the styloid process and adjoining part of the stylohyoid ligament to the side of the tongue. It pulls the tongue upwards and backwards (for details, see [Chapter 9](#) ).

### **Stylopharyngeus muscle**

It extends from medial side of the base of the styloid process to the posterior border of the lamina of the thyroid cartilage. It helps to elevate the larynx during swallowing and phonation (for details, see [Chapter 14](#) ).

## **Ligaments attached to styloid process**

### **Stylohyoid ligament**

It extends from tip of the styloid process to the lesser cornu of the hyoid bone.

### **Stylomandibular ligament**

It extends from the tip of the styloid process to the angle of ramus of the mandible. Sometimes it is pierced by the cervical part of the facial artery.

## **CLINICAL CORRELATION**

**Eagle syndrome:** Normally, the tip of styloid process is located between the external and internal carotid arteries, just lateral to the tonsillar fossa. The elongated styloid process or calcification of stylohyoid ligament can cause recurrent throat pain in the region of tonsillar fossa and upper neck, which radiates to the ipsilateral ear. It aggravates during swallowing. This clinical

condition is termed *styalgia* or *Eagle syndrome*.

## Lymphatic drainage of the head and neck AN 28.5

The knowledge of lymphatic drainage of the head and neck is extremely important because the cancers arising in this region have predictable patterns of spread through the chains of lymph nodes in the neck, which help the surgeons to remove the desired lymph nodes. The lymph nodes and other lymphoid tissues in the head and neck are often inflamed and produce swellings, which are examined by physicians in day-to-day practice. All the lymph from the region of head and neck drains into *deep cervical lymph nodes* either: (a) directly from the tissues or (b) indirectly after passing through the outlying groups of lymph nodes.

The efferents from deep cervical nodes form the **jugular trunk**, which on the right side drains into the **right lymphatic duct** and on the left side into the **thoracic duct**. The right lymphatic duct and thoracic duct generally empty into the junction of the subclavian and internal jugular veins on their respective sides.

### Lymph nodes AN 28.5

Of total 800 lymph nodes in the body, approximately 300 lymph nodes are located in the region of the head and neck only. The lymph nodes in the region of the head and neck are broadly classified into two groups: peripheral and terminal ([Fig. 16.21](#)).

**FIG. 16.21 ■** Lymph nodes of the head and neck.

## Peripheral lymph nodes

Peripheral lymph nodes (also called *outlying lymph nodes* ). They are usually found in groups, which are arranged in outer and inner circles (Fig. 16.22 ):

1. **Outer circle:** It is formed by lymph node groups, which form the **pericervical** or **cervical collar** at the junction of the head and neck (craniocervical junction) and extends from chin in front to the occiput behind. They include submental, submandibular, superficial parotid (preauricular), mastoid (postauricular), and occipital nodes.

### ◦ **Outlying extensions of lymph node groups of pericervical collar:**

- (a) *Facial nodes:* These are extensions of submandibular nodes and include:

- A small *buccal node* lying on the lateral surface of the buccinator along the facial vein.

- A small *mandibular node* , which is frequently present where facial vessels cross the lower border of the mandible.
  - A small *infraorbital node* lying just below the orbit.
- (b) *Superficial cervical nodes*: They are situated superficial to sternomastoid (upper part) along the external jugular vein. These are the extensions of parotid nodes.
- (c) *Anterior cervical nodes*: They are situated along the anterior jugular vein. One member of this group frequently lies in the suprasternal space (*suprasternal node*) . They are extensions of submental lymph nodes.
2. **Inner circle**: The inner circle is formed by the following lymph node groups, which lie deep to the investing layer of deep cervical fascia ([Fig. 16.22](#) ):
- (a) *Infrahyoid nodes*: These lie in front of thyrohyoid membrane.
  - (b) *Prelaryngeal nodes*: These are situated in front of the conus elasticus or cricothyroid membrane.
  - (c) *Pretracheal lymph nodes*: These lie in front of trachea below the isthmus of thyroid gland.
3. **Paratracheal nodes**: These nodes flank the trachea and oesophagus on either side along the recurrent laryngeal nerves.
4. **Retropharyngeal lymph node**: These lie posterior to pharynx and in front of prevertebral fascia in the retropharyngeal space ([Fig. 16.23](#) ).

**FIG. 16.22 ■** General plan of location of the lymph node groups in the region of the head and neck.

**FIG. 16.23** ■ Retropharyngeal lymph nodes.

### **N.B.**

Deep to inner circle, there is a submucosal ring of aggregated masses of lymphoid tissue called *tonsils*, which surround the commencement of air and food passages. These together constitute the *Waldeyer's lymphatic ring* (Fig. 16.24). The lymph from lymphoid tissue of this ring drains into pericervical chain and deep cervical chain, which constitutes the *external ring of Waldeyer*.

**FIG. 16.24** ■ Waldeyer's internal and external rings.

### Terminal/deep cervical lymph nodes

These are **deep cervical lymph nodes** that lie along and around the internal jugular vein, some within the carotid sheath and some on the surface of the sheath, under cover of sternocleidomastoid.

For the convenience of description, deep cervical lymph nodes are divided into upper and lower groups (superior and inferior deep cervical nodes), though there is no clear demarcation between them:

1. **Superior group of deep cervical lymph nodes:** They lie above the omohyoid. One lymph node of this group is situated below the posterior belly of digastric between the angle of the mandible and anterior border of the sternocleidomastoid in the triangle formed by posterior belly of digastric, facial vein, and internal jugular vein. It is called **jugulodigastric node**.
  - It drains the lymph primarily from the palatine tonsil. Therefore, it is also termed **lymph node of the tonsil**. When enlarged because of pathology in the palatine tonsil, it is easily palpable behind and below the angle of the mandible.
2. **Lower group of deep cervical lymph nodes:** One of the lymph

nodes of this group lies above the intermediate tendon of omohyoid posterior to the internal jugular vein. It is called **jugulo-omohyoid lymph node**. As this lymph node drains lymph primarily from the tongue, it is termed as **lymph node of the tongue**. This node lies deep to sternocleidomastoid, and therefore, can be palpated only if enlarged considerably.

◦ Some nodes of this group extend into the supraclavicular fossa and are related to brachial plexus and subclavian vessels. These are termed as **supraclavicular lymph nodes (Virchow's lymph nodes)**. The left supraclavicular lymph nodes are clinically important because they are common site of metastasis from malignant disease (cancer) of the stomach. The testicular and oesophageal cancers can also metastasize in these nodes. The Virchow's lymph nodes are often palpable in cancer stomach. One or two lymph nodes of this group lie in contact with accessory nerve at a higher level in the posterior triangle.

## CLINICAL CORRELATION

**Surgical neck dissection:** The cancers arising in the head and neck region from structures such as nasopharynx, paranasal air sinuses, oral cavity, oropharynx, larynx, and thyroid gland have predictable patterns of spread through the chains of lymph nodes in the neck. When operating to remove malignant lesion in this region, it is vitally important to understand these patterns of spread. The surgeons classify lymph nodes in neck into the following levels:

- **Level I nodes** are in the submental and submandibular triangles.
- **Level II nodes** lie around the upper portion of internal jugular vein and upper part of spinal accessory nerve. They extend from the base of the skull to the bifurcation of the common carotid artery or the hyoid bone.
- **Level III nodes** lie around the middle third of the internal jugular vein and extend from inferior border of level II to the intermediate tendon of omohyoid (cricoid cartilage).
- **Level IV nodes** lie around the lower third of the internal jugular vein and extend from lower border of level III to the clavicle. Thus, it includes supraclavicular lymph nodes.
- **Level V nodes** are in the posterior triangle of the neck, related to the spinal accessory nerve.

- **Level VI nodes** are nodes surrounding the midline visceral structures and include the pretracheal and paratracheal nodes.
- **Level VII nodes** are in the superior mediastinum. Knowing which levels of nodes are likely to be involved in the metastatic spread of a particular cancer, an appropriate nodal clearance is undertaken.

The **classical radical neck dissection** involves the removal of level I–V nodes and removal of the sternocleidomastoid muscle, internal jugular vein, and spinal accessory nerve.

The **modified radical neck dissection** (also called **functional neck dissection**) involves the removal of level I–V nodes but spares either or all of sternocleidomastoid muscle, internal jugular vein, and spinal accessory nerve.

The **selective neck dissection** involves some but not level I–V nodes.

### **Golden Facts to Remember**

• <b>Chief arteries of the head and neck</b>	Right and left common carotid arteries
• <b>Chief veins of the head and neck</b>	Right and left internal jugular veins
• <b>All the branches of subclavian artery (generally) arise from its first part</b>	Costocervical trunk on the right side, which arises from second part of that side
• <b>Largest branch of the first part of the subclavian artery</b>	Vertebral artery
• <b>Shortest branch of the subclavian artery</b>	Thyrocervical trunk
• <b>Most superficial part of the subclavian artery</b>	Third part
• <b>Most constant pulse in the body</b>	Carotid pulse/neck pulse
• <b>Anaesthetist's artery</b>	Superficial temporal artery
• <b>All lymph node groups of pericervical collar are paired except</b>	Submental group of lymph nodes, which is unpaired
• <b>Lymph node of tonsil</b>	Jugulodigastric lymph node
• <b>Lymph node of tongue</b>	Jugulo-omohyoid lymph node

## CLINICAL CASE STUDY

A 67-year-old man was keeping quite well until he suddenly developed weakness in his limbs on the right side. This lasted for approximately 12 h and then improved spontaneously and he recovered completely after 24 h. His family physician thought that he might have a *transient ischaemic attack in the brain (cerebral stroke)*. He was referred to a neurocentre by his family physician for thorough check-up by a neurosurgeon. On examination, the surgeon heard a bruit at the level of origin of common carotid artery on the left side. The colour *Doppler ultrasonographic scan* revealed more than 75% narrowing of the internal carotid artery at its origin. A carotid angiogram confirmed this narrowing. He was diagnosed as a case of **carotid artery stenosis due to atherosclerosis**.

### Questions

1. At what level does the common carotid terminate by dividing into internal and external carotid arteries?
2. What is **bruit** ?
3. What are the main relations at the bifurcation of common carotid artery?
4. Why does a patient develop signs of a cerebral stroke if there is formation of atheroma in the internal carotid artery?
5. What percentage of cerebral strokes are due to carotid stenosis?

### Answers

1. At the level of upper border of lamina of the thyroid cartilage.
2. It is a **noise of blood flow** produced when it passes through a narrowed vessel.
3. The common carotid artery is present in the carotid sheath containing internal jugular vein laterally and vagus nerve between and behind the artery and vein. The cervical sympathetic chain lies behind the carotid sheath on prevertebral fascia.
4. A portion of atheroma gets detached, and enters the middle cerebral artery and blocks it. This leads to cerebral ischaemia. Consequently, the patient develops the signs of **cerebral stroke**.
5. 10%–20%.

---

# Chapter 17: Nose and paranasal air sinuses

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the features of external and internal nose.
- Describe the features of nasal septum, lateral wall of nose, their blood supply and nerve supply. **AN 37.1**
- Describe location and functional anatomy of paranasal sinuses. **AN 37.2**
- The anatomical classification of paranasal air sinuses.
- Describe the anatomical basis of sinusitis and maxillary sinus tumours. **AN 37.3**
- Write short notes on: (a) nasal septum, (b) middle meatus of nose, (c) nasal conchae, and (d) lateral wall of nose.
- Give the anatomical basis of: (a) deviated nasal septum (DNS), (b) epistaxis, and (c) antral puncture (antrostomy).

## Nose

The nose is the uppermost part of the respiratory tract and contains the peripheral organ of smell.

It consists of the external nose and the nasal cavity. The Greek word for nose is *rhinos*. Thus, the study of the nose and its diseases is termed as *rhinology*.

## Functions

The functions of the nose are as follows:

1. Respiration
2. Olfaction
3. Protection of the lower respiratory passages
4. Air conditioning of the inspired air
5. Vocal resonance
6. Nasal reflex functions (e.g., sneezing).

A detailed knowledge of anatomy of the nose is essential to:

1. ENT and plastic surgeons to correct the various deformities of nose and enhance the looks of the face.
2. Physicians to treat diseases such as rhinitis, sinusitis, and respiratory diseases including asthma due to environmental pollution.

## External nose

### Features

The external nose is a pyramidal projection in the mid-face. It presents the following features ([Fig. 17.1](#)):

1. **Tip** (or apex), the lower free end
2. **Root or bridge**, the upper narrow part, which is continuous with the forehead
3. **Dorsum**, a round border between tip and root where sides of the nose meet
4. **Nostrils or nares**, the two piriform apertures at the broad lower end
5. **Alae**, the lower flared parts, one on either side of external nose.

**FIG. 17.1** ■ Features of the external nose. ( **A** ) Front view. ( **B** ) Lateral view.

## Skin

The skin covering the nose (nasal skin) is thin and loosely attached to the underlying structures, hence freely mobile. Over the apex and alae, it is thicker and more adherent and contains large sebaceous glands, whose orifices are usually very distinct. The hypertrophy of these sebaceous glands gives rise to a lobulated tumour – the **rhinophyma** . To some extent the skin extends into the vestibule of nose, where it contains variable number of stiff hairs (**vibrissae** ).

## Skeleton

The skeletal framework (Fig. 17.2 ) of the external nose is partly bony (upper one-third) and partly cartilaginous (lower two-third).

**FIG. 17.2 ■** Osseocartilaginous framework of the external nose. ( **A** ) Anterior view. ( **B** ) Lateral view. ( **C** ) Basal view.

**Bony framework of the nose :** It is formed by:

- (a) *Two nasal bones* (forming the **bridge of the nose** )
- (b) Frontal processes of the maxillae.

The two nasal bones meet in the midline and rest on the upper part of the nasal process of the frontal bone. They are held together between the frontal processes of the maxillae. The bony part of external nose terminates in front and below as the **piriform aperture** .

**Cartilaginous framework of the nose :** It is formed by **five main cartilages** and several additional tiny ones.

The five main cartilages of the nose are as follows:

1. Two lateral cartilages
2. A single median septal cartilage
3. Two major alar cartilages.

The lateral and major alar cartilages are also termed as **superior** and **inferior lateral cartilages** , respectively.

The cartilaginous framework is anchored to the piriform aperture by fibrous tissue.

The lateral cartilages, one on each side, articulate above with margin of piriform aperture formed by the frontal process of maxilla and the nasal bone and below with the major alar cartilage. Medially, it is continuous by a narrow bridge with the septal cartilage.

The major alar cartilage is U-shaped and comprises medial and lateral crura. The medial crura of two sides meet in the midline below the lower margin of the septal cartilage to form the lower part of the nasal septum called **columella** .

The anterosuperior border of septal cartilage runs from under the nasal bones to the tip of the nose. It supports the dorsum of the cartilaginous part of the nose.

The lateral crus of major alar cartilage extends into the ala of the nose but does not reach the bony margin; the gap is filled by fibrofatty tissue and

minor alar cartilages.

In addition to five main cartilages of the nose, there are two or more tiny cartilages, which lie above and lateral to major alar cartilage on either side and termed as **minor alar (or sesamoid ) cartilages** . They are of no functional and clinical significance.

## CLINICAL CORRELATION

- **Nasal fractures:** Because the nose is the most projecting part of the face, the fractures of nasal bones are common facial fractures.
- The **medial and lateral crura of major alar cartilage** maintain the patency of the nostril (Fig. 17.2 ). The angle between the medial and lateral crura is variable, being acute in high narrow noses, and obtuse in low broad noses with flaring alae. This anatomical fact is of great significance in plastic surgery of the nose.

## Internal nose/nasal cavity

The interior of the nose (also called internal nose) is divided into right and left nasal cavities by a nasal septum (Fig. 17.3 A).

**FIG. 17.3 ■** Interior of the nose. ( **A** ) Division of the internal nose into right and left nasal cavities. ( **B** ) Communication of nasal cavity to exterior through nostril and to nasopharynx through choana.

Each nasal cavity communicates with the exterior through nostril (or naris) and with the nasopharynx through the posterior nasal aperture (or the choana; Fig. 17.3 B). Each nasal cavity is divided into two portions: (a) a small anteroinferior part lined by skin – the **vestibule** and (b) a large posterosuperior part lined by mucosa – the **nasal cavity proper** .

### **Vestibule of nose**

It is the anteroinferior part of nasal cavity, lined by skin. The skin contains sebaceous glands, hair follicles, and the stiff interlacing hair called **vibrissae** . Its upper limit on the lateral wall of nasal cavity is marked by **limen nasi** . Its medial wall is formed by a mobile **columella** .

### **Nasal cavity proper**

#### **Boundaries**

The nasal cavity proper presents the following boundaries:

1. Roof
2. Floor
3. Medial wall (septum)
4. Lateral wall.

#### **Roof of nose**

The roof is very narrow in front and widens to approximately 1 cm near the choanae. It is horizontal in the middle third, where it is formed by the cribriform plate of the ethmoid. Through this, olfactory nerves enter the cranial cavity from the nasal cavity.

The anterior third of roof slopes downwards and forwards. It is formed by the nasal spine of the frontal, the nasal bone, and the junction of the septal

and lateral cartilages. The posterior third of the roof also slopes downwards and backwards ([Fig. 17.3 B](#)). It is formed by the anterior surfaces of the body of the sphenoid.

### Medial wall of the nose

The medial wall of the nose is smooth vertical septum which divides the inside of nose into two chambers.

### Lateral wall of the nose

The lateral wall of the nose is irregular and essential for humidifying the air we breathe. All the paranasal sinuses open in it.

### Lining of nasal cavity

The lining of the various regions of nasal cavity ([Fig. 17.4](#)) is as follows:

1. **Vestibule:** It is lined by the skin containing a large number of sebaceous glands and interlacing coarse hair – the **vibrissae**. As the air passes through the nostrils, the large particles of dust in the air are trapped by the vibrissae.
2. **Olfactory region:** The upper third of the nasal cavity bounded above by cribriform plate of ethmoid, laterally by superior nasal concha and medially by upper one-third of the nasal septum forms the olfactory region. It is lined by the *olfactory epithelium*, which contains receptor cells for smell. Here mucous membrane is paler in colour.
3. **Respiratory region:** The rest of the nasal cavity (lower two-third) is lined by the *respiratory epithelium*, that is pseudostratified ciliated columnar epithelium with goblet cells. The respiratory mucosa is highly vascular and contains a large number of cavernous spaces and sinusoids to warm the air. In addition, it contains a large number of serous and mucous glands. The secretion of the serous glands makes the air moist, whereas the secretion of the mucous glands traps the dust and other particles. Furthermore, the cilia on the surface of the mucous membrane sweep the mucous posteriorly into the pharynx. From where it is swallowed and eliminated by the GIT.

**FIG. 17.4 ■** Lining of the nasal cavity.

### **N. B.**

Because of the presence of cilia in the epithelial lining and secretions of the serous and mucous glands in the nasal cavity, the air while passing through the nasal cavity is not only filtered but also moistened and humidified, a mechanism that protects the lower respiratory tract.

### **Arterial supply of nasal cavity**

The nasal cavity is supplied by both external and internal carotid arteries. The branches of external carotid artery include sphenopalatine, greater palatine, lateral nasal and superior labial while those of internal carotid artery include anterior and posterior ethmoidal arteries.

### **Venous drainage of nasal cavity**

The veins draining the nasal cavity form plexus beneath the mucosa and in general accompany the arteries. The veins of nasal cavity drain into facial vein, pterygoid venous plexus, and pharyngeal venous plexus.

### **N. B.**

- The submucous venous plexus is more marked in the region of Little's area.

- The *retrocolumellar* vein runs vertically downwards, crosses the floor of nasal cavity to join the venous plexus on the lateral wall. This is the common site of venous bleeding in young individuals.

### Lymphatic drainage of nasal cavity

Lymph from anterior half of nasal cavity (both medial and lateral walls) is drained into *submandibular lymph nodes* and from posterior half into *retropharyngeal lymph nodes*.

### Nerve supply of nasal cavity

The nasal cavity is supplied by the following nerves:

1. **Olfactory nerves:** They carry sense of smell from olfactory region of nasal cavity (for details, see [Chapter 22](#) ).
2. **Nerves of general sensation:** These are as follows:
  - (a) Anterior ethmoidal nerve
  - (b) Branches of sphenopalatine ganglion
  - (c) Branches of infraorbital nerve.

They carry sensations of pain, touch, and temperature from respiratory region and vestibule of nasal cavity.
3. **Autonomic nerves:** Both parasympathetic and sympathetic fibres supplying nasal cavity are derived from vidian nerve (nerve of pterygoid canal) through pterygopalatine ganglion.

The parasympathetic fibres supply nasal glands and control nasal secretion. The sympathetic fibres, on stimulation, cause vasoconstriction.

### CLINICAL CORRELATION

**Rhinitis:** It is the inflammation of mucous membrane lining the nasal cavity. The hypertrophy of mucosa over inferior concha is a common feature of *allergic rhinitis*. Clinically, it presents as nasal blockage, sneezing, and water discharge from nose (*rhinorrhoea*).

The *excessive rhinorrhoea* due to *vasomotor and allergic rhinitis* can be controlled by sectioning the vidian nerve.

### Floor of nose

The floor is almost horizontal. It is formed by the upper surface of the hard palate, that is, anterior three-fourth is formed by palatine process of maxilla

and posterior one-fourth is formed by the horizontal plate of the palatine bone.

### Medial wall of nose/nasal septum AN 37.1

It is formed by **nasal septum**. The nasal septum is a median osseocartilaginous partition between the two nasal cavities. It is seldom exactly in the median plane but bulges to one or the other side, more frequently to the right.

The **bony part** is formed by (Fig. 17.5 ):

- (a) Perpendicular plate of ethmoid, which forms the posterosuperior part of the septum
- (b) Vomer, which forms the postero-inferior part of the septum.

#### N.B.

In addition, the nasal spine of frontal bone, crest formed by nasal bones, sphenoidal crest and nasal crest formed by the fusion of palatine processes of maxillae and horizontal plates of palatine bones also contribute a bit in the formation of nasal septum.

**FIG. 17.5** ■ Formation of the nasal septum.

The **cartilaginous part** is formed by (Fig. 17.5 ):

- (a) Septal cartilage, which forms the major anterior part of the septum and fits in the angle between the vomer and perpendicular plate of ethmoid
- (b) Septal processes of the two major alar cartilages.

### **N. B.**

The septal processes (medial crura) of two major alar cartilages are united together in the midline by a fibrous tissue to form *columella* (also called *columellar septum* ).

Between the columella and caudal border of the septal cartilage, a small portion of septum is made up of double layer of the skin with no bony or cartilaginous support. This part is referred to as *membranous septum*.

Both columellar and membranous parts are freely movable from side to side.

### **Arterial supply of nasal septum AN 37.1**

The nasal septum is supplied by the following arteries (Fig. 17.6 ):

1. Septal branch of the anterior ethmoidal artery (a branch of ophthalmic artery).
2. Septal branch of the posterior ethmoidal artery (a branch of ophthalmic artery).
3. Septal branch of the sphenopalatine artery (a branch of maxillary artery).
4. Septal branch of the greater palatine artery (a branch of maxillary artery).
5. Septal branch of the superior labial artery (a branch of facial artery).

**FIG. 17.6 ■** Arterial supply of the nasal septum.

### **Nerve supply of nasal septum (Fig. 17.7 ) AN 37.1**

The nasal septum receives supply from the following nerves:

1. **Olfactory nerves** supply the upper part (one-third) just below the cribriform plate.
2. **Internal nasal branch** of the anterior ethmoidal nerve, a branch from nasociliary, supplies the anterosuperior part.
3. **Nasopalatine nerve**, a branch of pterygopalatine ganglion, supplies the posteroinferior part.
4. Medial posterior superior nasal branches of pterygopalatine ganglion supply the posterosuperior part.
5. Nasal branch of greater palatine nerve supplies the posterior part.
6. **Anterior superior alveolar nerve**, a branch of maxillary nerve, supplies the anteroinferior part.

**FIG. 17.7 ■** Nerve supply of the nasal septum.

## CLINICAL CORRELATION

- **Deviated nasal septum (DNS):** The deviated nasal septum is not uncommon and is an important cause of nasal obstruction. The males are affected more than females. It occurs because of numerous factors such as trauma and developmental error. If DNS is severe and causing mechanical obstruction, leading to difficulty in breathing sinusitis, headache, excessive snoring, and so on, it is corrected by submucous resection (SMR) or septoplasty. (For details, consult ENT textbooks.)
- The septal cartilage not only forms partition between the right and left nasal cavities but also provides support to the dorsum of the anterior two-third of the nose. Therefore, its destruction due to disease or excessive removal in submucous resection leads to supratip depression of the external nose.

## CLINICAL CORRELATION

**Little's area and Anterior nose bleeding:** It is an area in the anteroinferior part of the nasal septum just above the vestibule. It is highly vascular. Here the septal branches of the anterior ethmoidal sphenopalatine, greater palatine, and superior labial arteries anastomose to form a vascular plexus called *Kiesselbach's plexus*.

This area of nasal septum is the commonest site of **epistaxis (nose**

**bleeding)** in children and young adults. The causes of bleeding are finger nail trauma while picking the nose and so on. (**Note:** In children and young adults, mild epistaxis usually occurs because of fingernail trauma following picking of the nose leading to tear of veins in the vestibule of nose.)

## Lateral wall of nose AN 37.1

The lateral wall of the nose (Fig. 17.8) is complicated. It is formed by a number of bones and cartilages (Fig. 17.8).

The **bones** forming the lateral wall are as follows:

- (a) Nasal
- (b) Frontal process of maxilla
- (c) Lacrimal
- (d) Conchae and labyrinth of ethmoid
- (e) Inferior nasal concha
- (f) Perpendicular plate of palatine
- (g) Medial pterygoid plate of sphenoid.

The **cartilages** forming the lateral wall are as follows:

- (a) Lateral nasal cartilage (upper nasal cartilage)
- (b) Major alar cartilage (lower nasal cartilage)
- (c) Three to four tiny cartilages of the alae (minor alar cartilages)

**FIG. 17.8** ■ Formation of the lateral wall of the nasal

cavity. Note the bones reducing the size of large maxillary hiatus of disarticulated skull. *Red circle* indicates the position of maxillary air sinus in disarticulated skull.

### Features of lateral wall of nose (Fig. 17.9 )

The lateral wall is divided into the following three areas:

1. **Anterior part** presents a small, depressed area, the **vestibule** . It is lined by the skin containing **vibrissae** (short, stiff curved hair).
2. **Middle part** is known as **atrium of the middle meatus** . It is limited above by a faint ridge of mucous membrane, the **agger nasi** . The curved mucocutaneous junction between the atrium and vestibule is known as **limen nasi** .
3. **Posterior part** presents three scroll-like projections, the **conchae or turbinates** . The spaces separating the conchae are called **meatuses** .

**FIG. 17.9** ■ Features of the lateral wall of the nasal cavity.

### Main Features of Lateral Wall of Nose

The **conchae and meatuses** form the main features of the lateral wall:

**Conchae** (also called **turbinates** ) are the curved bony projections directed downwards and medially. Below and lateral to each concha is a corresponding **meatus** . From above downwards, the conchae are superior, middle, and inferior nasal conchae. Sometimes a fourth concha, the concha suprema is also present.

**Conchae:**

- Superior and middle nasal conchae are the projections from the medial surface of the ethmoidal labyrinth.
- Inferior concha is an independent bone.
- The superior concha is smallest and inferior concha is largest in size.

**Meatuses:**

◦Meatuses are the passages (recesses) beneath the overhanging conchae. They are visualized once conchae are removed.

1. **Inferior meatus** is the largest and lies underneath the inferior nasal concha.
2. **Middle meatus** lies underneath the middle concha. It presents the following features:
  - (a) *Ethmoidal bulla* (bullae ethmoidalis), a round elevation produced by the underlying middle ethmoidal sinuses.
  - (b) *Hiatus semilunaris* , a deep semicircular sulcus below the bullae ethmoidalis.
  - (c) *Infundibulum* , a short passage at the anterior end of middle meatus.
3. **Superior meatus** is the smallest and lies below the superior concha.

A triangular depression, above and behind the superior concha is known as the **sphenoethmoidal recess** .

**Openings of the lateral wall of nose (Fig. 17.10 )**

The lateral wall of the nose has number of openings. These are listed in [Table 17.1](#) .

**FIG. 17.10 ■** Lateral wall of the nose with conchae removed showing openings of various air sinuses and nasolacrimal duct.

**TABLE 17.1**

### Openings in the lateral wall of the nose

Sites	Openings
<b><i>Sphenoethmoidal recess</i></b>	Opening of the sphenoidal air sinus
<b><i>Superior meatus</i></b>	Opening of the posterior ethmoidal air sinuses
<b><i>Middle meatus</i></b>	Opening of the middle ethmoidal air sinuses
• On bulla ethmoidalis	
• In hiatus semilunaris – Anterior part – Middle part – Posterior part	Opening of the frontal air sinus Opening of the anterior ethmoidal air sinuses Opening of the maxillary air sinus

## ***Inferior meatus***

Opening of the nasolacrimal duct (in the anterior part of meatus)

### **Arterial supply of lateral wall AN 37.1**

The arterial supply (Fig. 17.11) of the various parts of the lateral wall is as follows:

1. **Anterosuperior quadrant**, by the anterior ethmoidal artery, a branch of ophthalmic artery
2. **Anteroinferior quadrant**, by branches of facial and greater palatine arteries
3. **Posterosuperior quadrant**, by sphenopalatine artery, a branch of maxillary artery
4. **Posteriorinferior quadrant**, by branches of greater palatine artery, which pierces the perpendicular plate of palatine

**FIG. 17.11** ■ Arterial supply of the lateral wall.

### **CLINICAL CORRELATION**

**Posterior nose bleeding.** It commonly occurs in elderly or old people due to rupture of vascular plexus due to hypertension. This plexus is located in the posterior part of inferior meatus called Woodruff's area. The following arteries usually anastomose in this area: pharyngeal, sphenopalatine,

posterior nasal, posterior septal arteries.

It is stopped by posterior nasal packing. The posterior nasal bleeding is dangerous as the blood is often swallowed in oropharynx.

### **Nerve supply of lateral wall AN 37.1**

The following nerves supply (Fig. 17.12 ) different parts of the lateral wall:

1. **Olfactory nerves** supply the upper part (one-third) just below the cribriform plate of ethmoid up to the superior concha.
2. **Anterior ethmoidal nerve** (from ophthalmic) supplies the anterosuperior quadrant.
3. **Anterior superior alveolar nerve** , a branch of infraorbital nerve (from maxillary), supplies the anteroinferior quadrant.
4. **Posterior superior lateral branches** , of pterygopalatine ganglion, supply posterosuperior quadrant.
5. **Nasal branches of greater palatine nerve** (from pterygopalatine ganglion) supply posteroinferior quadrant.

**FIG. 17.12 ■** Nerve supply of the lateral wall of the nose.

## CLINICAL CORRELATION

**Examination of the nasal cavity (rhinoscopy):** The nasal cavity can be examined in the living individual either through the nostril (**anterior rhinoscopy**) or through the pharynx (**posterior rhinoscopy**).

(a) **Anterior rhinoscopy:** It is carried out by inserting a nasal speculum through a nostril. The following features are visualized by this method:

- ⊖ Middle and inferior conchae
- ⊖ Superior middle and inferior meatuses
- ⊖ Nasal septum
- ⊖ Floor of the nasal cavity.

(b) **Posterior rhinoscopy:** It is carried out by inserting a mirror into the pharynx (Fig. 17.13 A). The following features can be visualized by this method (Fig. 17.13 B):

- ⊖ Choanae
- ⊖ Conchae
- ⊖ Posterior border of the nasal septum.

**FIG. 17.13** ■ Posterior rhinoscopy. ( **A** ) Showing placement of mirror in the nasopharynx. ( **B** ) Structures seen in the mirror.

## Paranasal air sinuses AN 37.2

The paranasal air sinuses are air-containing cavities in the paranasal bones, that is, bones around the nasal cavity. The paranasal air sinuses develop as mucosal diverticula of the main nasal cavity invading the adjacent bones. Therefore, they are lined by a **pseudostratified ciliated columnar epithelium** (respiratory epithelium) as in the nasal cavity ([Fig. 17.14](#)).

**B**

**FIG. 17.14 ■** Positions of paranasal air sinuses on the surface. ( **A** ) Front view. ( **B** ) Side view.

## Classification

There are four **paranasal air sinuses** on each side and are named after the bones containing them, namely

1. **Frontal air sinuses** present in the frontal bone
2. **Ethmoidal air sinuses** present in the ethmoid bone
3. **Maxillary air sinuses** present in the maxilla
4. **Sphenoidal air sinuses** present in the sphenoid bone.

All paranasal air sinuses except ethmoidal are arranged in pairs, one on either side of midline. The ethmoidal air sinuses are arranged in three groups, namely anterior, middle, and posterior on each side of midline.

The bony orbit serves as a landmark to appreciate the location of various paranasal air sinuses.

**Relationship of the paranasal sinuses to the orbit it is as follows (Fig. 17.15 ):**

- The frontal air sinus *above* the orbit
- The maxillary air sinus *below* the orbit
- The ethmoidal air sinus *medial* to the orbit
- The sphenoidal air sinus *behind the orbit* .

**FIG. 17.15** ■ Schematic diagram to show the location of various paranasal sinuses in relation to the orbit.

### Development

The paranasal sinuses develop as diverticula of respiratory part of nasal cavity into surrounding bone.

### Features

These are as follows:

- (a) All open into nasal cavity.
- (b) All are lined by respiratory epithelium, that is pseudostratified ciliated columnar epithelium.

(c) All are supplied by trigeminal nerve.

### **N.B.**

- The sinuses exhibit two spurts of growth, namely:  
First around 7–8 years (during the eruption of the teeth) and second at puberty.
- All the paranasal air sinuses are present in rudimentary form at birth *except* the frontal air sinuses, which start developing 2 or 3 years after birth.

### **Functions**

Paranasal air sinuses perform the following functions:

1. Make the skull lighter
2. Add resonance to the voice
3. Act as air conditioning chambers by adding humidity and temperature to the inspired air
4. Aid in the growth of facial skeleton after birth

### **CLINICAL CORRELATION**

**Sinusitis: AN 37.3** The inflammation of the tissue lining the paranasal air sinuse is called sinusitis. It is caused by common cold, allergy, infection, and so on.

Clinically, it presents as headache, blocked or stuffy nose and persistent thick purulent discharge from the nose.

In standard radiological images, normal paranasal air sinuses are radiolucent, whereas diseased paranasal sinuses show varying degree of opacity. The newer imaging techniques, namely CT scan provides very clear images of the sinuses, which significantly aid in diagnosis ([Fig. 17.16](#) ).

**FIG. 17.16 ■** Coronal CT scan showing ethmoidal and maxillary air sinuses. (Source : Fig. 8.281, page 1029, *Gray's Anatomy for Students* , Richard L Drake, Wayne Vogl, Adam WM Mitchell. Copyright Elsevier Inc. 2005, All rights reserved.)

### **N.B.**

Clinically, the sinuses are divided into the following two main groups:

1. **Anterior group:** It includes those sinuses, which drain into the middle meatus, namely frontal, anterior and middle ethmoidal and maxillary sinuses.
2. **Posterior group:** It includes those sinuses which do not drain into the middle meatus, namely posterior ethmoidal and sphenoidal air sinuses.

## Frontal air sinuses

The frontal air sinus (two in number) lies between the inner and outer tables of the frontal bone deep to medial part of the superciliary arch. They are triangular in shape. The right and left air sinuses are usually unequal in size and rarely symmetrical. The right air sinus is frequently larger than the left and separated from it by a septum.

Each sinus drains into the anterior part of the hiatus semilunaris of the middle meatus through frontonasal duct.

### Measurements

*Vertical: 3 cm*

*Transverse: 2.5 mm*

*Anteroposterior: 1.8 cm.*

### Relations

*Anterior wall is related to:* Superciliary arch of forehead

*Posterior wall is related to:* Meninges and frontal lobe of the brain

*Inferior wall is related to:* Roof of nose, roof of orbit (medial part) and ethmoidal air cells

### Nerve supply

It is by supraorbital nerve.

### CLINICAL CORRELATION

**Frontal sinusitis:** Infection of frontal air sinus may spread posteriorly into the anterior cranial fossa causing *frontal lobe abscess* or downwards into the orbit leading to *orbital cellulitis*.

The pain of frontal sinusitis is usually severe and localized over the affected sinus (*frontal headache*). It shows characteristic periodicity, that is, it starts on waking, gradually increases and reaches its peak by about midday, and then starts subsiding. It is also referred to as *office headache* because of its presence during office hours.

## Maxillary air sinus (antrum of highmore)

It is the largest of paranasal air sinuses and is present in the body of maxilla with approximately 15 ml volume.

It drains into the hiatus semilunaris (posterior part) of the middle meatus.

## Development

The maxillary sinus is first to develop. It appears approximately in the 4th month of intrauterine life as an out-pouching from the mucous membrane lining the lateral wall of the nasal cavity. It is rudimentary at birth, enlarges rapidly during 6–7 years, and becomes fully developed at puberty after the eruption of permanent teeth.

## Measurements

*Vertical: 3.5 cm*

*Transverse: 2.5 cm*

*Anteroposterior: 3.25 cm.*

## Shape

It is pyramidal in shape with the base directed medially towards the lateral wall of the nose and its apex laterally towards the zygomatic bone.

## Relations (Fig. 17.17 )

**Roof** is formed by the floor of the orbit and contains infraorbital canal.

The infraorbital nerve and artery traverse the roof in this bony canal.

**Floor** (very small) is formed by the alveolar process of maxilla and lies approximately 1.25 cm below the floor of the nasal cavity. The level of the floor corresponds to the level of the ala of nose. Normally, the roots of the 1st and 2nd molar teeth project into the floor producing elevations, but sometimes roots of the 1st and 2nd premolars, 3rd molar and rarely even that of canine may project into the floor. Sometimes roots of teeth are separated from the sinus only by a thin layer of mucous lining.

**Base** is formed by the lateral wall of the nose. It possesses two important structures: (a) Ostium of maxillary sinus and (b) nasolacrimal duct.

◦The *opening or ostium for drainage of the sinus* is located in its upper part, that is close to the roof, a *disadvantageous position for natural drainage*.

◦In disarticulated skull, medial surface of the body of maxilla presents a large opening – the **maxillary hiatus, which is**

***considerably reduced in size by overlapping of the following bones (Fig. 17.5 ):***

1. Uncinate process of ethmoid from above
2. Descending process of lacrimal from in front
3. Lacrimal and ethmoidal process of inferior nasal concha, from below
4. Perpendicular plate of palatine from behind.

**N.B.**

The *nasolacrimal duct* lies in the osseous canal formed by the maxilla, lacrimal bone and inferior nasal concha. It opens into the inferior meatus beneath the inferior nasal concha.

**Apex** extends into the zygomatic process of maxilla.

**Anterior wall** is formed by the anterior surface of the body of maxilla and is related to infraorbital plexus of nerves. Within this wall, the *anterosuperior alveolar nerve* runs in a curved bony canal called **canalis sinuosus** .

**Posterior wall** is formed by the infratemporal surface of the maxilla, separating the sinus from infratemporal and pterygopalatine fossae. It is pierced by the *posterosuperior alveolar nerves and vessels* .

**FIG. 17.17 ■** Relations of maxillary sinus.

### Opening

Maxillary sinuses open in the hiatus semilunaris of middle meatus near the roof of the sinus.

### Arterial supply

It is by the anterior, middle, and posterosuperior alveolar arteries from maxillary and infraorbital arteries.

### Lymphatic drainage

The sinus drains into submandibular lymph nodes.

### Nerve supply

Maxillary sinuses are supplied by the anterior, middle, and posterior superior alveolar nerves from the maxillary and infraorbital nerves.

## CLINICAL CORRELATION AN 37.3

- **Maxillary sinusitis:** Maxillary sinus is the most commonly infected of

all the sinuses because of the following reasons:

- ⊖ Infection can reach into this sinus from infected nose (viral rhinitis), carious upper premolar and molar teeth, especially molars and infected frontal and anterior ethmoidal sinuses.
- ⊖ Being most dependent part, it acts as a **secondary reservoir** for pus from frontal air sinus through frontonasal duct and hiatus semilunaris.
- ⊖ Pain of maxillary sinusitis is referred to the upper teeth and infraorbital skin because of common innervation by the maxillary nerve.

• **Drainage of maxillary sinus:** The opening of this sinus is unfortunately located in the upper part of the lateral wall of nose, which is a disadvantageous site for adequate natural drainage. Surgically, maxillary sinus is drained in the following two ways:

- ⊖ *Antral puncture (antrostomy)* by using trocar and cannula, which are passed below the inferior nasal concha in an outward and backward direction ([Fig. 17.18](#)).
- ⊖ Fenestrating the antrum through canine fossa in the gingivolabial sulcus (**Caldwell –Luc operation**).

• **Maxillary sinus tumour (carcinoma of maxillary sinus):** It arises from the mucous lining of the sinus. It is an aggressive tumour usually diagnosed at an advanced stage, hence has poor prognosis. The signs and symptoms produced by the invasion of the carcinoma can be easily remembered anatomically:

- ⊖ The *upward invasion* into the orbit displaces the eyeball causing **proptosis** (protrusion of eyeball) and **diplopia** (double vision).
  - Involvement of infraorbital nerve produces pain and anaesthesia in the skin over the face below the orbit.
- ⊖ The *downward invasion* into the floor produces *visible bulge* or even ulceration of palatal roof of the oral cavity.
- ⊖ The *medial invasion* encroaches the nasal cavity causing obstruction and **epistaxis**. The obstruction of nasolacrimal duct in this wall produces epiphora (overflow of tears).
- ⊖ The *lateral invasion* produces swelling on the face and palpable mass in the gingivolabial fold (groove).
- ⊖ *Backward (posterior) invasion* may involve the palatine nerves leading to severe referred pain to the upper teeth.

**FIG. 17.18** ■ Antral puncture (antrostomy).

## Ethmoidal air sinuses

The ethmoidal air sinuses are made up of a number of air cells present within the labyrinth of ethmoidal bone; thus, they are located between the upper part of the lateral nasal wall and medial wall of the orbit.

They are divided into the following three groups:

1. **Anterior** , consisting of up to 11 cells
2. **Middle** , consisting of 1–3, usually 3 cells
3. **Posterior** , consisting of 1–7 cells

The first two groups – *anterior and middle* – drain into the middle meatus (anterior opens in the hiatus semilunaris and middle on the surface of bulla ethmoidalis) and the *posterior* into posterior part of superior meatus.

## CLINICAL CORRELATION

**Ethmoidal sinusitis:** It is often associated with infection of other sinuses. The pain is localized over the bridge of nose medial to the eye.

The ethmoidal air sinuses are separated from the medial wall of the orbit only by a very thin plate of bone called *lamina papyracea* ; therefore, the infection from these sinuses can easily spread into the orbit producing *orbital cellulitis* .

## Sphenoidal air sinuses

The right and left sphenoidal air sinuses lie within the body of the sphenoid bone above and behind the nasal cavity. They are separated from each other by a bony septum. The two air sinuses are usually asymmetrical. Each sinus drains into the sphenoethmoidal recess of the nasal cavity.

### Measurements

*Vertical: 2 cm*

*Transverse: 1.5 cm*

*Anteroposterior: 2 cm*

### Relations

*Above:* Pituitary gland and optic chiasma

*Below:* Roof of the nasopharynx

*Lateral:* Cavernous sinus and internal carotid artery (on each side)

*Behind:* Pons and medulla oblongata

*In front:* Sphenoethmoidal recess

### CLINICAL CORRELATION

**Sphenoidal sinusitis:** Isolated *sphenoidal sinusitis* is rare. It is usually a part of pansinusitis or is associated with the infection of posterior ethmoidal air sinuses.

The infection of sphenoidal air sinuses spreading upwards may affect the pituitary gland and optic chiasma.

### Golden Facts to Remember

• <b>Whole nasal cavity is respiratory in function except</b>	Upper one-fourth, which is olfactory in function
• <b>All the conchae are parts of ethmoid bone except</b>	Inferior nasal concha, which is an independent bone
• <b>Commonest site of nose bleeding</b>	Little's area
• <b>Artery of nose bleeding</b>	Septal branch of the sphenopalatine artery
• <b>Rhinologist's artery</b>	Septal branch of the sphenopalatine artery

• <b>Woodruff's area</b>	Vascular area under the posterior end of inferior nasal concha; it is the site of <del>posterior epistaxis</del>
• <b>Largest paranasal air sinus</b>	Maxillary air sinus
• <b>First sinus that can be visualized radiologically after birth</b>	Maxillary air sinus (4–5 months after birth)
• <b>Most commonly infected paranasal air sinus</b>	Maxillary sinus
• <b>All the paranasal air sinuses are present at birth <i>except</i></b>	Frontal air sinuses, which start developing at the age of 2 years
• <b>Most easily naturally drained paranasal air sinus</b>	Frontal air sinus
• <b>Most deeply located paranasal air sinuses</b>	Sphenoidal air sinuses
• <b>Only bone in the body, made up solely of spongy bone</b>	Inferior nasal concha

## CLINICAL CASE STUDY

A 12-year-old boy while playing in the school ground during the lunch break suddenly started bleeding from nose. His mates took him to the principal's office where teachers tried to stop the bleeding by pinching the nose and pouring cold water on the nose. When bleeding did not stop, the student was taken to the nearby dispensary. The doctor diagnosed him a case of **nose bleeding**. He packed his nose with gauze soaked with Gelfoam, and Floseal, ready made nasal packs are also easily available to stop bleeding and sent back the boy to the school.

### Questions

1. What is the commonest cause of nose bleeding in children?
2. What is Little's area and which arteries anastomose in this area?
3. Which artery is called the artery of nose bleeding?
4. What is commonest cause of nose bleeding in elderly?

## Answers

1. In vast majority of children, nose bleeding occurs because of digital trauma to the anastomosis of arterioles and veins (Kiesselbach's plexus) in Little's area.
2. Area on nasal septum just above the nasal vestibule. The arteries anastomosing in this area are septal branches of the sphenopalatine, greater palatine, anterior ethmoidal, and superior labial arteries.
3. Septal branch of the sphenopalatine artery.
4. Rupture of *Woodruff's vascular plexus* located in the posterior part of inferior meatus of nasal cavity (called Woodruff's area).

---

# Chapter 18: Ear: External ear, middle ear, pharyngotympanic tube and internal ear

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the parts, blood supply, and nerve supply of external ear. **AN 40.1**
- Describe the middle ear under the following headings: (a) location and shape, (b) boundaries, (c) relations, (d) contents, (e) nerve supply, and (f) applied anatomy. **AN 40.2**
- Describe the auditory tube. **AN 40.2**
- Describe the features of internal ear. **AN 40.3**
- Describe the anatomical basis of otitis externa and otitis media. **AN 40.4**
- Give the anatomical basis of myringotomy. **AN 40.5**
- Write short notes on: (a) tympanic membrane, (b) external auditory meatus, (c) parts of internal ear, (d) ear ossicles, and (e) nerve supply of pinna.
- Enumerate: (a) layers of tympanic membrane, (b) parts of internal ear, and (c) contents of middle ear.
- Draw the labelled diagrams to show: (a) external surface of tympanic membrane as seen through otoscope, (b) lateral surface of the auricle, and (c) medial wall of the middle ear.

The ear is the organ of hearing and plays an important role in maintaining the balance (equilibrium) of the body. The ear is divided into three parts ([Fig. 18.1](#)

), namely

1. External ear
2. Middle ear
3. Internal ear.

**FIG. 18.1** ■ The ear and its subdivisions (external, middle, and internal ear).

The external ear consists of auricle or pinna and external auditory meatus, at the medial end of which lies the tympanic membrane or eardrum, separating external ear from middle ear. The middle ear or tympanic cavity is a small air-filled space within petrous part of the temporal bone containing auditory ossicles. It communicates with the nasopharynx through auditory tube. By its medial wall, the middle ear adjoins the internal ear. The internal ear consists of a bony labyrinth, a complicated space, also in the petrous part of the temporal bone containing fluid-filled membranous labyrinth. The membranous labyrinth contains sensory receptors for hearing and balancing.

The sensations of hearing and balancing from these receptors are carried out by vestibulocochlear nerve to the cerebral cortex for interpretation.

## External ear AN 40.1

The external ear consists of two parts: (a) pinna or auricle and (b) external auditory meatus, which are concerned with collection and transmission of sound waves to the tympanic membrane, respectively.

### **Auricle/pinna**

The auricle is trumpet-like undulating projection on the side of the head ([Fig. 18.2](#)). The entire pinna except its lobule is made up of a single piece of crumpled yellow elastic cartilage covered with skin ([Fig. 18.2 B](#)). The lobule of pinna is made of fibrofatty tissue covered with skin. The auricular cartilage is continuous with the cartilage of the external auditory meatus.

**FIG. 18.2 ■ Auricle.** (A) Features on the lateral surface of the auricle. (B) Crumpled elastic cartilage of the auricle.

## Surfaces

The auricle presents two surfaces: lateral and medial.

### Lateral surface

The **lateral surface** of auricle ([Fig. 18.2 A](#)) displays the following elevations and depressions:

1. **Concha** , a large depression that leads into the external auditory meatus. It is guarded in front by a triangular flap of cartilage, the **tragus** .
2. **Helix** forms a prominent peripheral rim of the pinna. It consists of two limbs: anterior and posterior. An anterior limb ends as **crus of helix** , which divides the concha into smaller upper and larger lower parts. The posterior limb ends below as flabby ear lobe and its upper end sometimes presents a small elevation called **Darwin's tubercle** . Probably, it is erroneously thought to represent the vestige of the pointed part of the quadruped ear.
3. **Antihelix** is another prominent ridge present in front and parallel to the posterior part of helix, partly encircling the concha. Its upper end divides into two crura enclosing a triangular depression called **triangular fossa** . The narrow gutter between the helix and antihelix is called **scaphoid fossa** .
4. **Tragus** is a small triangular flap in front of concha.
5. **Antitragus** is a small elevation opposite to tragus from which it is separated by an **intertragic notch** .
6. **Cymba conchae** is a small area of concha above the crus of helix. Clinically, it is important as it corresponds to the suprameatal triangle (McEwen's triangle) of mastoid process.
7. **Lobule** of the ear hangs below the antitragus as a large skin covered flap of fibrofatty tissue.

### **N.B.**

- There is no cartilage between tragus and crus and the gap between the two is called *incisura terminalis*.
- The thick hair on pinna particularly on tragus in male represents Y-linked inheritance.
- The pinna collects and directs the sound waves to the external auditory meatus.

### **Medial surface**

The **medial/cranial surface** of (pinna) presents the following features:

1. **Eminentia concha** , which corresponds to the depression of the concha.
2. **Eminentia triangularis** , which corresponds to the triangular fossa between the crura of the antihelix.

## CLINICAL CORRELATION

- Pinna is a source of several graft materials for the surgeons.
- The lobule of ear is commonly pierced for wearing ear rings.
- For surgery of external auditory meatus, incision is made in the region of incisura terminalis because it will not cut through the cartilage.

## Muscles

The muscles of the auricle are divided into two groups: extrinsic and intrinsic. They are rudimentary in humans.

The **extrinsic muscles** pass from scalp or skull to the auricle. They are as follows:

1. Auricularis anterior
2. Auricularis superior
3. Auricularis posterior.

The anterior and superior muscles arise from epicranial aponeurosis and are inserted into the upper part of the helix and upper part of the cranial surface of the auricle, respectively. The auricularis posterior arises from the mastoid process and gets inserted into eminentia concha.

The **intrinsic muscles** are small muscular slips, which pass between the cartilaginous parts of the auricle.

## Actions

The extrinsic muscles may play a role in positioning of the auricle to catch the sound, whereas intrinsic muscles may change the shape of the auricle. Such movements are rarely seen in human beings. However, in animals, they modify the shape of the pinna.

## Skin

The skin covering the auricle is closely adherent to the underlying cartilage and fibrofatty tissue. Sometimes coarse hair projects out of the tragus,

antitragus, intertragic notch, and helix in elderly males. The hairy pinna is an expression of Y-linked genes.

### **Arterial supply AN 40.1**

1. The cranial surface (medial) and posterior part of the lateral surface are supplied by the posterior auricular branch of the external carotid artery.
2. The anterior part of the lateral surface is supplied by the superficial temporal artery.

### **N.B.**

Few branches of occipital artery supply the upper part of the cranial surface.

### **Venous drainage**

The veins accompany the arteries and drain into superficial temporal and external jugular veins.

### **Lymphatic drainage**

The lymph from auricle drains into:

1. Preauricular (parotid) lymph nodes
2. Mastoid lymph nodes
3. Upper group of deep cervical lymph nodes.

### **Nerve supply (Fig. 18.3 ) AN 40.1**

*Motor supply:* All extrinsic and intrinsic muscles of the auricle are supplied by the facial nerve. The auricularis anterior and auricularis superior are supplied by the temporal branch of the facial nerve, whereas auricularis posterior is supplied by the posterior auricular branch of the facial nerve.

*Sensory supply (Fig. 18.3 ):*

1. Lateral (facial) surface (Fig. 18.3 A)
  - (a) Lower one-third, by great auricular nerve (C2, C3)
  - (b) Upper two-third, by auriculotemporal nerve (a branch of mandibular division of the trigeminal nerve [5th cranial nerve])
  - (c) Concha, by auricular branch of the vagus (Alderman's nerve)

nerve (10th cranial nerve)

2. Medial (cranial) surface (Fig. 18.3 B)

(a) Lower one-third, by great auricular nerve (C2, C3)

(b) Upper two-third, by lesser occipital nerve (C2)

(c) Eminentia conchae, by auricular branch of the vagus.

**FIG. 18.3** ■ Sensory supply of the auricle: (A) lateral surface and (B) medial surface.

### **CLINICAL CORRELATION**

**Involvement of pinna in herpes zoster of geniculate ganglion (Ramsay Hunt syndrome):** Clinically, it is acknowledged that a few fibres of the facial nerve accompany auricular branch of vagus and supply skin in the region of concha and eminentia conchae, as vesicles are seen in these regions during involvement of the geniculate ganglion of the facial nerve by herpes zoster virus. The communication between the auricular branch of vagus and facial nerves takes place within the petrous temporal bone.

### **External auditory meatus (Fig. 18.1 )**

The external auditory meatus (synonym for external acoustic meatus) extends from the bottom of the concha to the tympanic membrane and

measures approximately 24 mm along its posterior wall.

Note that it is not a straight tube but it has a typical S-shaped course. Its outer part is directed upwards, backwards, and medially (UBM); whereas its inner part is directed downwards, forwards, and medially (DFM). *Therefore, to examine the tympanic membrane, the pinna has to be pulled upwards, backwards, and laterally, to bring the two parts in alignment .*

## Parts

The external auditory meatus is divided into two parts: cartilaginous and bony.

The **cartilaginous part** forms the outer one-third (8 mm) of the meatus. The cartilage is the continuation of the cartilage of the auricle. The skin covering the cartilaginous part is thick, and contains hair and ceruminous (pilosebaceous) glands, which secrete ear wax.

The **bony part** forms the inner two-third (16 mm) of the external auditory meatus. The skin lining the bony part of meatus is thin and continuous with the cuticular layer of the tympanic membrane. It is devoid of hair and ceruminous glands. Approximately 4 mm lateral to the tympanic membrane (approximately 20 mm deep to concha), the bony meatus presents a narrowing called **isthmus** . The foreign body lodged medial to isthmus gets impacted and is difficult to remove.

Sometimes anterior wall of bony part presents a foramen (**foramen of Huschke** ), permitting infection back and forth from parotid gland. This foramen is normally present in children up to the age of 4 years.

In a newborn, the bony canal is not developed and represented by a tympanic ring of bone. Consequently, the external auditory meatus is shorter in children, and therefore deep insertion of ear speculum may damage the tympanic membrane.

## Arterial supply AN 40.1

The external auditory meatus is supplied by the following arteries:

1. Posterior auricular artery, a branch of the external carotid artery
2. Deep auricular artery, a branch of first part of the maxillary artery
3. Anterior tympanic artery, a branch of first part of the maxillary artery.

## Nerve supply AN 40.1

1. Roof and anterior wall are supplied by the auriculotemporal nerve.

2. Floor and posterior wall are supplied by the auricular branch of vagus (note that it is the only cutaneous branch of the vagus nerve).

## CLINICAL CORRELATION

- **Otitis externa: AN 40.4** It is the infection of outer part of external auditory meatus. It is often caused by water remaining in the ear after swimming. The moist environment helps bacteria and fungi to grow.
- **Infection and boils of the external auditory meatus:** They cause very little swelling but are very painful because the skin lining is firmly adhered to the underlying cartilage and bone.
- **Furuncles in external auditor meatus:** The hairs are confined to the outer part of the external auditory meatus; hence, the *furuncles* (infection of hair follicles) develop only in this part.
- **Examination of external auditory meatus and tympanic membrane:** To do this, the pinna is pulled upwards, backwards, and laterally (vide supra) in adults, whereas in infants, it is pulled downwards and backwards. This is because in infants, the bony part of external auditory meatus is not developed and tympanic membrane is directed mainly downwards.
- **Ear wax:** It prevents injury of the lining epithelium of the external auditory meatus from water and the damage of tympanic membrane by trapping the insects. The excess of ear wax interfering with hearing is removed by syringing. The irritation of auricular branch of vagus during syringing may reflexly produce persistent cough called **ear cough**, vomiting and even death due to sudden cardiac inhibition.
- **Aldermen's nerve:** The *Aldermen* were the individuals in ancient Rome, who were very fond of excessive eating and used to stimulate their jaded appetite by dropping cold water or spirit behind the ear because this could reflexly stimulate gastric peristalsis because of supply of this area by the auricular branch of vagus nerve, which also supplies motor innervation to the GIT.

## Development

The external auditory meatus develops as an ectodermal invagination of first pharyngeal cleft. It becomes filled with ectodermal cells forming a solid mass called *meatal plug*, which is canalized before birth. The auricle develops from

six mesodermal tubercles around the external opening of the first pharyngeal cleft. The failure of canalization of meatal plug results in **atresia of the external auditory meatus**, whereas failure of fusion of tubercles will give rise to **accessory auricles**.

## Tympanic membrane

The tympanic membrane (or eardrum) is a thin (0.1 mm thick) semitransparent membrane, which forms the partition between external acoustic meatus and middle ear. It is oval, measuring 9–10 mm in length, and 8–9 mm in width. It is placed obliquely making an angle of approximately 55 degrees with the floor of the external acoustic meatus. The tympanic membrane faces downwards, forwards, and laterally as though to catch the sounds reflected from the ground. Consequently, anterior wall and floor of external auditory meatus are longer than the posterior wall and the roof.

## Structure

The tympanic membrane is made of three layers (Fig. 18.4); from lateral to medial, these are as follows:

1. **Outer cuticular layer** of stratified squamous epithelium, which is continuous with the skin lining the external auditory meatus.
2. **Middle fibrous layer**, which encloses the handle of the malleus. It contains outer radiating and inner circular fibres.
3. **Inner mucosal layer** is lined by low columnar epithelium, which is continuous with the mucous lining of the middle ear.

## FIG. 18.4 ■ Layers of the tympanic membrane.

### Parts

The tympanic membrane is divided into two parts: pars tensa and pars flaccida.

**Pars tensa** forms most of the tympanic membrane. Its periphery is thickened to form a fibrocartilaginous rim called **annulus tympanicus**, which fits into the tympanic sulcus. The fibrocartilaginous rim presents a notch above. From margins of the notch, anterior and posterior malleolar folds in mucous membrane of tympanic cavity pass to gain attachment to the lateral process of the malleus. The handle of the malleus is firmly attached to the inner surface of the pars tensa. This part is rendered tough by the inward pull of the tensor tympani muscle, attached to the root of handle of the malleus and radial fibres.

**Pars flaccida (Shrapnell's membrane)** is a small triangular area above the lateral process of malleus between *anterior and posterior malleolar folds* (now called *malleal folds*). This part is thin and lax because intermediate fibrous layer here is replaced by loose areolar tissue. It appears slightly pinkish.

### Surfaces

**Lateral surface** of the tympanic membrane is concave towards the meatus and directed downwards, forwards, and laterally.

**Medial surface** is convex and bulges towards the middle ear. The point of maximum convexity is called **umbo** (Fig. 18.5). When the tympanic membrane is illuminated for inspection, concavity of the membrane produces a *cone of light* radiating from the umbo over the anteroinferior quadrant. This surface receives the attachment of malleus up to the centre of the membrane. Here the handle of the malleus is crossed medially by chorda tympani nerve, which runs forwards between the fibrous and mucosal layer at the junction of pars flaccida and pars tensa.

**FIG. 18.5 ■ Tympanic membrane (schematic diagram).**  
 (A) External surface of tympanic membrane as seen through otoscope: 1, posterosuperior quadrant; 2, anterosuperior quadrant; 3, posteroinferior quadrant; 4, anteroinferior quadrant. (B) Medial surface of tympanic membrane showing the course of the chorda tympani nerve.

## Arterial supply

1. The outer surface is supplied by deep auricular artery, a branch from first part of maxillary artery.
2. The inner surface is supplied by (a) anterior tympanic artery, a branch from first part of maxillary artery and (b) posterior tympanic artery, a branch from stylomastoid artery arising from posterior auricular artery.

## Venous drainage

1. Veins from outer surface drain into external jugular vein.
2. Veins from inner surface drain into transverse sinus and pterygoid venous plexus.

## Nerve supply

1. Anterior half of the lateral surface is supplied by the auriculotemporal nerve (V3).
2. Posterior half of the lateral surface by the auricular branch of vagus (10th cranial nerve).
3. Medial surface by tympanic branch of the glossopharyngeal (9th cranial nerve) through tympanic plexus.

## CLINICAL CORRELATION

- **Perforation of the tympanic membrane:** It may result from an external injury or middle ear infection (otitis media). It may lead to middle ear deafness.
- **Examination of tympanic membrane:** Inspection of the tympanic membrane with an otoscope provides significant information about the condition of the middle ear. The colour, curvature, presence of lesions, and position of malleus are features of special importance. When tympanic membrane is illuminated for examination, a cone of light is reflected in the anteroinferior quadrant of the membrane from umbo, the point of maximum concavity, which marks the attachment of the handle of the malleus. As the membrane is semitranslucent, the following structures lying deep to it can be seen ([Fig. 18.6](#)):
  - *Handle of malleus* , as a yellow streak extending from umbo upwards and forwards.
  - *Lateral process of malleus* , as a white prominence in the upper part

of the streak of handle of malleus.

- *Long processes of incus* , as white streaks behind and parallel to the upper part of the handle of malleus.
- A cone of light at 5-o'clock position in anteroinferior quadrant.

### • Myringotomy AN 40.5

The myringotomy is a surgical incision into the eardrum to drain fluid or pus from middle ear.

Clinically, the tympanic membrane is divided into four quadrants by means of two imaginary lines passing through the umbo. One is drawn along the handle of the malleus and the other at right angle to it through the umbo (Fig. 18.5 A).

On illumination, normal membrane looks pearly grey. Sometimes an incision is given in the tympanic membrane (*myringotomy* ) to drain the pus from the middle ear. The incision is usually given in the posteroinferior quadrant to avoid injury to the chorda tympani nerve, which crosses the inner aspect of the membrane in the upper part.

**FIG. 18.6 ■** Otoscopic view of the tympanic membrane.

(Source : Fig. 8.109 B, page 857, *Gray's Anatomy for Students* , Richard L Drake, Wayne Vogl, Adam WM

## Development

The tympanic membrane develops from first pharyngeal membrane consisting from superficial to deep of three layers: ectoderm, mesoderm, and endoderm.

Therefore, the tympanic membrane also consists of three layers from superficial to deep, which are as follows:

1. *Cuticular layer* , derived from ectoderm
2. *Intermediate layer* , derived from mesoderm
3. *Mucous layer* , derived from endoderm.

The three layers of tympanic membrane are likened to the three layers of *trilaminar embryonic disc* .

## Middle ear AN 40.2

The middle ear (synonym for tympanum, tympanic cavity) is a narrow slit-like air-filled cavity within the petrous part of the temporal bone. The middle ear is sandwiched between external and internal ear.

*It contains three auditory ossicles, which transmit sound vibrations from tympanic membrane in its lateral wall to the internal ear via its medial wall.*

The tympanic cavity is really the intermediate portion of a blind diverticulum from the respiratory mucous membrane of the nasopharynx.

From front to back, the diverticulum consists of pharyngotympanic tube, tympanic cavity, and mastoid antrum.

In a section through long axis of petromastoid bone, the outline of tympanic cavity together with mastoid antrum and pharyngotympanic tube resembles a *pistol* , the nozzle being represented by the tube, the body by tympanic cavity, and handle by mastoid antrum ([Fig. 18.7](#) ).

**FIG. 18.7** ■ Section through long axis of the petromastoid bone showing pharyngotympanic tube, middle ear (tympanic cavity), and mastoid antrum. Figure in the inset on the right side shows pistol.

### Size and shape

The middle ear is shaped like a cube, compressed from side to side. In coronal section, it resembles a biconcave disc like a red blood cell (Fig. 18.8 ).

**FIG. 18.8** ■ The shape and dimensions of the middle ear cavity.

## Measurements

• Vertical diameter	15 mm
• Anteroposterior diameter	15 mm
• Transverse diameters	
(a) At roof	6 mm
(b) In the centre	2 mm
(c) At the floor	4 mm

## Communication

The middle ear communicates:

*Anteriorly:* with nasopharynx through pharyngotympanic tube

*Posteriorly:* with mastoid antrum and mastoid air cells through aditus to

antrum called **aditus ad antrum**.

## Contents of the middle ear

*Inside the mucous lining:*

1. Air

*Outside the mucous lining:*

1. Three small bones called ear ossicles: malleus, incus, and stapes
2. Two muscles: tensor tympani and stapedius
3. Two nerves: chorda tympani and tympanic plexus
4. Vessels supplying and draining the middle ear
5. Ligaments of the ear ossicles.

### **N.B.**

The mucous membrane lining of the middle ear invests all the structures within it and forms several folds, which project into the cavity giving it a honeycomb appearance.

Thus, strictly speaking, the middle ear contains only air.

## Subdivisions of the middle ear (Fig. 18.9 )

The tympanic cavity extends much beyond the limits of tympanic membrane, which forms its lateral boundary. It is divided into three parts, namely

1. **Epitympanum (attic )**, a part above the tympanic membrane containing head of malleus, body, and short process of incus.
2. **Mesotympanum**, a part opposite to tympanic membrane containing handle of malleus, long process of incus and stapes. It is the narrowest part of the middle ear.
3. **Hypotympanum**, a part below the tympanic membrane.

**FIG. 18.9** ■ Subdivisions of the middle ear.

### **Boundaries (Fig. 18.10 )**

The middle ear is likened to a six-sided box and thus presents six walls, namely:

1. Roof
2. Floor
3. Anterior wall
4. Posterior wall
5. Medial wall
6. Lateral wall.

**FIG. 18.10** ■ Schematic diagram to show the boundaries (and their relations) of the middle ear. The middle ear is likened to a six-sided box and its lateral side is opened out.

O, oval window; P, pyramid; PC, processus cochleariformis; PM, promontory; R, round window; S, sinus tympani; TP, tympanic plexus.

## Roof

It is formed by a thin plate of bone called **tegmen tympani**. It separates the tympanic cavity from the middle cranial fossa. The tegmen tympani also extends posteriorly to form the roof of **aditus ad antrum**.

## Floor

The floor is also formed by a thin plate of bone, which separates the tympanic cavity from the jugular bulb. Sometimes, it is congenitally deficient and the jugular bulb then projects into the middle ear, being separated from cavity only by mucosa.

The *tympanic branch* of glossopharyngeal nerve pierces the floor between the jugular fossa and lower opening of the carotid canal and enters the tympanic cavity to take part in the formation of tympanic plexus.

### **Anterior wall**

It is formed by a thin plate of bone. In the lower part, it separates the cavity from internal carotid artery. The upper part of anterior wall presents two openings or canals, the upper one for the tensor tympani muscle and the lower one for the auditory tube.

The bony partition between the two canals extends backwards along the medial wall in the tympanic cavity as a curved lamina called **processus cochleariformis** .

### **Posterior wall**

The posterior wall separates the tympanic cavity from mastoid antrum and mastoid air cells, and presents the following features:

1. **Aditus ad antrum** , an opening in the upper part through which tympanic cavity communicates with the mastoid antrum.
2. **Fossa incudis** , a small depression close to the aditus, lodging the short process of the incus.
3. **Pyramid** , a hollow conical bony projection below the aditus containing stapedius muscle whose tendon appears through its summit, passes forwards to be attached to the neck of the stapes.
4. **Vertical part of facial canal** runs in the posterior wall just behind the pyramid and descends up to the stylomastoid foramen.
5. **Posterior canaliculus for chorda tympani** , a small aperture for emergence of this nerve.

### **Medial wall**

It separates tympanic cavity from the internal ear; thus, it is actually formed by the bony lateral wall of the internal ear. The medial wall presents the following features:

1. **Promontory** , a rounded prominence in the centre produced by first (basal) turn of the cochlea. The tympanic branch of the glossopharyngeal nerve ramifies on it to form **tympanic plexus** .
2. **Oval window (fenestra vestibuli)** , a reniform aperture located

above and behind the promontory. It is closed by the base of stapes and annular ligament.

3. **Round window (fenestra cochleae)**, a small round opening below and behind the promontory, which in life is closed by fibrous secondary tympanic membrane. The secondary tympanic membrane separates the middle ear from the scala tympani.
4. **Sinus tympani**, a depression behind the promontory between fenestra vestibuli and fenestra cochleae, which indicates the position of ampulla of the posterior semicircular canal.
5. **Prominence of oblique part of the facial canal** that extends backwards and downwards above the oval window until it joins vertical part of the facial canal in posterior wall of the tympanic cavity. Sometimes the bony covering of the facial nerve may be absent, thus exposing the nerve for injuries and infection.
6. **Prominence of lateral semicircular canal of the internal ear**, which is seen as a small ridge high up in the angle between medial and posterior walls.

### Lateral wall

Most of the lateral wall is formed by **tympanic membrane**, which separates the tympanic cavity from the external auditory meatus (Fig. 18.10).

The **chorda tympani nerve**, a branch of facial nerve passes across the tympanic membrane lying lateral to the long process of the incus and medial to the handle of the malleus.

It enters tympanic cavity through posterior canaliculus in the posterior wall and leaves through the anterior canaliculus medial to the petrotympanic fissure.

### CLINICAL CORRELATION AN 40.4

- **Otitis media (infection of the middle ear):** It is common especially in infants and children. Infective agents reach the middle ear from the upper respiratory tract through pharyngotympanic tube.
  - ↳ In **acute otitis media**, a surgical incision is given in the lower and posterior part of tympanic membrane to drain the pus collected in the middle ear.
  - ↳ The long-standing infection leads to **chronic suppurative otitis media (CSOM)**. The spread of infection from the middle ear may

give rise to the following clinical conditions:

- *Acute mastoiditis and mastoid abscess* , when infection spreads into mastoid antrum and mastoid air cells through aditus ad antrum in the posterior wall.
  - *Meningitis and temporal lobe abscess* may occur, if infection spreads upwards through the thin roof (tegmen tympani).
  - *Lower motor neuron type of facial palsy* , when infection erodes the papery thin bony wall of facial canal.
  - *Transverse and sigmoid sinus thrombosis* , when infection spreads to them.
  - *Labyrinthitis* , when infection spreads deep into medial wall. The labyrinthitis causes *vomiting and vertigo*.
  - *Cerebellar abscess* , when infection spreads too far posteromedially.
- **Chronic otorrhoea:** If pus is not drained in CSOM, then the spontaneous rupture of tympanic membrane leads to **chronic otorrhoea**.

## Ear ossicles

The three ear ossicles (malleus, incus, and stapes) within the middle ear are connected to one another by synovial joints and form a bony chain that extend across the tympanic cavity from the tympanic membrane to the oval window ([Fig. 18.11](#) ). They conduct sound vibrations from tympanic membrane to the oval window and subsequently to the inner ear fluid.

**FIG. 18.11 ■** Ear ossicles.

## Malleus

It resembles a hammer and, therefore, known as *malleus*. It has head, neck, handle (manubrium), a lateral process, and an anterior process. The head and neck lie in the epitympanum, whereas the handle is embedded in the fibrous layer of tympanic membrane. The lateral process forms a knob-like projection on the outer surface of the tympanic membrane and provides attachment to the anterior and posterior malleolar folds.

The head of malleus articulates with the body of the incus forming the *incudomalleolar joint (saddle type of synovial joint)*.

## Incus

It resembles an anvil or a premolar tooth in shape. It consists of a relatively large body and two slender processes: a short process and a long process. The body and short process lie in the attic, whereas its long process hangs vertically behind and parallel with the handle of the malleus.

Its bulbous tip (lentiform nodule) is directed medially to articulate with the head of the stapes, forming the *incudostapedial joint (ball and socket type of synovial joint)*.

## Stapes

It resembles a stirrup. It consists of head, neck, anterior and posterior crura, and footplate. The footplate closes the oval window and is attached to its margin by annular ligament. The features of ear ossicles are summarized in [Table 18.1](#) .

 **TABLE 18.1**

### Features of three ear ossicles

	<b>Malleus</b>	<b>Incus</b>	<b>Stapes</b>
<b><i>Resemblance</i></b>	Hammer	Anvil or premolar tooth	Stirrup
<b><i>Development</i></b>	1st pharyngeal arch cartilage	1st pharyngeal arch cartilage	2nd pharyngeal arch cartilage
<b><i>Muscle attached</i></b>	Tensor tympani	None	Stapedius
<b><i>Joint/joints</i></b>	Incudomalleolar (saddle type of synovial joint)	Incudomalleolar and incudostapedial	Incudostapedial (ball and socket type of synovial joint)

## Intratympanic muscles

There are two intratympanic muscles: **tensor tympani** and **stapedius** .  
The features of these muscles are enumerated in [Table 18.2](#) .

 **TABLE 18.2**

### Origin, insertion, nerve supply, and actions of the intratympanic muscles

<b>Muscle</b>	<b>Origin</b>	<b>Insertion</b>	<b>Nerve supply</b>	<b>Actions</b>
<b><i>Tensor tympani</i></b>	Cartilaginous part of the auditory tube and greater wing of sphenoid and upper part	Medial aspect of the upper end of	Mandibular nerve (V3)	Tenses the tympanic membrane

	of temporal bone	handle of malleus		
<b>Stapedius</b>	Interior of hollow pyramidal eminence on the posterior wall of tympanic cavity	Posterior aspect of the neck of stapes	Facial nerve (7th cranial nerve)	Draws the stapes laterally thus tilting its footplate in the oval window

## CLINICAL CORRELATION

- **Hyperacusis:** Both tensor tympani and stapedius contract reflexly and simultaneously to dampen very loud sounds, thus preventing noise trauma to the internal ear. The paralysis of stapedius results in *hyperacusis* (an abnormally increased power of hearing) where even whisper appears as noise.
- **Otosclerosis:** Abnormal ossification of annular ligament, which anchors the footplate of stapes to the oval window, is called *otosclerosis*. This impedes the movements of stapes and causes deafness. *The otosclerosis is the most common cause of conductive deafness in adults.*

## Arterial supply

The middle ear is supplied by six arteries, namely:

1. Anterior tympanic branch of the maxillary artery
2. Stylomastoid branch of the posterior auricular artery
3. Petrosal branch of the middle meningeal artery, running along the greater petrosal nerve
4. Superior tympanic branch of the middle meningeal artery, running along the canal for tensor tympani
5. Branch from the artery of pterygoid canal
6. Tympanic branch of the internal carotid artery.

## N.B.

Of the six arteries, first two – anterior tympanic branch of the maxillary and stylomastoid branch of the posterior auricular artery – are the main source

of the blood supply.

## Venous drainage

The veins from middle ear drain into:

1. Pterygoid venous plexus, via squamotympanic fissure
2. Superior petrosal sinus, through subarcuate fossa.

## Lymphatic drainage

The lymphatics from middle ear drain into:

1. Retropharyngeal lymph nodes
2. Parotid lymph nodes
3. Upper deep cervical lymph nodes.

## Nerve supply

1. **Tympanic branch of glossopharyngeal nerve:** It enters the middle ear through a canaliculus in the floor of the tympanic cavity and takes part in the formation of tympanic plexus.
  - It provides **sensory supply** to the lining of middle ear, antrum, and auditory tube.
  - Its preganglionic parasympathetic fibres supply the secretomotor fibres to the parotid gland.
2. **Superior and inferior caroticotympanic nerves:** They are vasomotor and derived from sympathetic plexus around the internal carotid artery.
3. **Facial nerve:** It runs in the bony canal along the medial and posterior walls of tympanic cavity and gives rise to three branches, namely
  - (a) *Chorda tympani nerve*, which: (i) carries taste sensations from anterior two-third of the tongue except vallate papillae, and (ii) provides secretomotor fibres to submandibular and sublingual salivary glands
  - (b) *Greater petrosal nerve*, which provides secretomotor fibres to lacrimal, nasal, and palatal mucous glands.
  - (c) *Nerve to stapedius muscle*.
4. **Mandibular nerve:** It provides motor fibres to tensor tympani muscle.

## Tympanic plexus

It is a plexus of nerves on the promontory in the medial wall of the middle ear. It is formed by:

- (a) *Tympanic branch of the glossopharyngeal nerve (Jacobson's nerve)*
- (b) *Superior and inferior caroticotympanic nerves* derived from sympathetic plexus around the internal carotid artery
- (c) *Branch from facial ganglion (geniculate ganglion).*

The tympanic plexus supplies mucous membrane of the middle ear, mastoid air cells, and bony eustachian tube. The lesser petrosal nerve derived from it contains secretomotor fibres of glossopharyngeal nerve to supply the parotid gland via otic ganglion.

### CLINICAL CORRELATION

**Referred pain of ear:** As middle ear and external ear are supplied by the branches of trigeminal (5th cranial nerve), glossopharyngeal (9th cranial nerve) and vagus (10th cranial nerve) nerves, the pain in the ear (*otalgia*) is often referred to other areas supplied by these nerves, for example, tongue, teeth, tonsil, and pharynx.

## Mastoid antrum

It is a large air-containing space in the upper part of the mastoid process. It communicates anteriorly with tympanic cavity through aditus ad antrum. Its roof is formed by **tegmen antri**, which is the backward continuation of **tegmen tympani**. It separates the antrum from middle cranial fossa. The lateral wall of the antrum is formed by a plate of bone, which is on an average 1.5 cm thick in the adult. (It is only 2 mm thick in a newborn.) It is marked on the surface of mastoid by suprameatal triangle (McEwen's triangle).

The floor of antrum receives the openings of mastoid air cells. Its posterior wall is related to sigmoid sinus, whereas its medial wall presents bulging of the lateral semicircular canal.

## Development

Mastoid antrum develops as a backward extension of tympanic cavity and assumes the full adult size at birth.

### CLINICAL CORRELATION

**Mastoid abscess:** It is a common condition. The antrum is approached surgically through its lateral wall. Thus, it is important to assess the limits of *suprameatal triangle*. This triangle is bounded *above* by supramastoid crest, *anteroinferiorly* by posterosuperior segment of bony external auditory meatus, and *posteriorly* by a line drawn as a tangent to the posterior margin of the bony meatal opening.

## Pharyngotympanic tube (Fig. 18.12 ) AN 40.2

The pharyngotympanic tube (auditory tube) is an osseocartilaginous tube, which connects the nasopharynx with tympanic cavity (middle ear). It is directed downwards, forwards, and medially from the tympanic cavity to the nasopharynx.

### FIG. 18.12 ■ Pharyngotympanic tube.

The auditory tube maintains equilibrium of air pressure on either side of the tympanic membrane for its proper vibration.

The pharyngotympanic tube is described in detail in [Chapter 14](#) , page 206.

### Development of the middle ear

The **auditory tube and middle ear** develop from **endodermal tubotympanic recess** , which arises from the 1st pharyngeal pouch (and partly from 2nd pharyngeal pouch). The mastoid antrum develops as an extension of the middle ear cavity into the mastoid process.

The **malleus and incus** develop from **mesoderm of the 1st arch** . The stapes develops from mesoderm of the 2nd arch except its foot plate and annular ligament, which are derived from otic capsule.

### Internal ear AN 40.3

The internal ear consists of a closed system of fluid-filled intercommunicating membranous sacs and ducts called **membranous labyrinth** . The fluid filled in the membranous labyrinth is called **endolymph** . The membranous labyrinth lies within the similar complex of intercommunicating bony cavities and canals (**bony labyrinth** ) in the petrous part of the temporal bone. The space between the membranous and bony labyrinth is filled with fluid called **perilymph** . The sensory receptors within the membranous labyrinth are responsible for hearing and balancing (equilibrium).

### Components of the internal ear

The internal ear consists of two components, namely:

1. Membranous labyrinth
2. Bony labyrinth.

### Membranous labyrinth (Fig. 18.13 )

The membranous labyrinth consists of the following four parts ([Fig. 18.12 A](#)):

1. Cochlear duct
2. Sacculus
3. Utricle

4. Semicircular ducts (three).

**FIG. 18.13** ■ Membranous labyrinth. ( **A** ) Schematic diagram to show separate four parts of labyrinth. ( **B** ) Complete labyrinth.

The *cochlear duct* lies within the bony *cochlea* , the *saccule* and *utricle* lie within the bony *vestibule* , and *three semicircular ducts* lie within the *three bony semicircular canals* .

These four parts are interconnected as follows:

1. The cochlear duct (basal turn) is connected to saccule by *ductus reuniens* .
2. The saccule and utricle are connected to each other by Y-shaped *utrículo-sacculus duct* , which expands to form *ductus and saccus endolymphaticus* .
3. The utricle is connected to three semicircular ducts through five openings.

### **N.B.**

#### **Sensory receptors of ear:**

- The sensory receptor within cochlear duct is ***spiral organ of Corti*** . It is concerned with *hearing* .
- The sensory receptors within saccule and *utricle* are ***maculae*** . They are concerned with *static balance* .
- The sensory receptors within the semicircular ducts are ***cristae ampullaris***. They are concerned with *kinetic balance* .

The sensations from cristae (kinetic balance) and maculae (static balance) are carried by vestibular nerve, whereas sensations of hearing from spiral organ are carried by the cochlear nerve ([Fig. 18.14](#) ).

**FIG. 18.14** ■ Sensory receptors in different parts of the membranous labyrinth and nerves, which carry sensations from them.

### Cochlear duct (scala media)

The cochlear duct is a spiral anterior part of the membranous labyrinth having two- and three-fourth turns. It lies in the middle part of the cochlear canal between scala vestibuli and scala tympani. The cochlear duct contains **spiral organ of Corti**, which is sensory receptor for hearing.

### Structure

The structure of cochlear duct is best studied in cross-section of the cochlear canal. In cross-section, the cochlear duct is triangular in shape ([Fig. 18.15](#)).

**FIG. 18.15** ■ Cross-section of the cochlear canal showing boundaries of the cochlear duct and organ of Corti within it.

## Boundaries

**Base:** Formed by the osseous spiral lamina (medially) and basilar membrane (laterally).

**Roof:** Formed by the vestibular membrane (Reissner's membrane), which passes from upper surface of spiral lamina to the wall of cochlea.

**Laterally:** It is bounded by the outer wall of cochlear canal.

## Spiral organ of corti

It is the peripheral organ of hearing in the cochlear duct and is situated on the basilar membrane. The important components of the organ of Corti are as follows:

1. **Tunnel of Corti:** It is formed by the inner and outer rod cells. It contains a fluid called *corticolymp*. The exact function of *rods* and *corticolymp* is not known.

2. **Hair cells:** These are receptor cells of hearing located on basilar membrane and their apices possess stereocilia (hair), which are overlaid by *tectorial membrane*. The inner cells are flask shaped and arranged in a single row, whereas outer cells are cylindrical and arranged in three or four rows. When sound vibrations (in fact fluid waves) pass from perilymph of scala vestibuli to the perilymph of scala tympani, the basilar membrane bulges and the overlying hair cells are stimulated. The inner hair cells are richly supplied by the cochlear nerve fibres and are responsible for transmission of auditory impulses. The outer hair cells are innervated by efferent fibres from the olivary complex and are concerned over modulation function of inner hair cells.
3. **Supporting cells (Deiter's and Hansen's Cells):** The Deiter's cells are situated between the outer hair cells and provide support to the latter. The Hansen's cells lie outside the hair cells.
4. **Membrana tectoria:** It is made up of gelatinous substance and overlies the hair cells. Medially, it is attached to osseous spiral lamina. The shearing force between the hair cells and tectorial membrane stimulate the hair cells.

### **N.B.**

The scala vestibuli and scala tympani containing perilymph lie above and below basilar membrane, respectively. Therefore, cochlear duct (containing endolymph) is bathed above and below by the perilymph within the two scala. The two scala are continuous with each other through a narrow opening at the apex of cochlear duct called *helicotrema* ([Fig. 18.16](#)).

**FIG. 18.16** ■ Parts of the bony labyrinth.

### Innervation of hair cells of organ of corti

Ninety-five per cent of afferent fibres (peripheral processes of bipolar neurons of spiral ganglion) supply the inner hair cells, whereas only 5% supply the outer hair cells. The spiral ganglion is located in the spiral canal within the modiolus near the base of the spiral lamina. The central processes of ganglion cells form the cochlear nerve.

Efferent fibres to the outer hair cells come from olivocochlear bundle. Their cell bodies are located in the superior olivary complex.

### Sacculle and utricle

The *sacculle* , a small globular membranous sac, lies in the anteroinferior part of the vestibule. The utricle is an oblong membranous sac and larger than the sacculle. It lies in the posterosuperior part of the vestibule.

The sacculle is connected in front to the basal turn of cochlear duct by the **ductus reuniens** and behind with the utricle by a Y-shaped **utriculo-saccular duct** . The vertical limb of 'Y' continues as endolymphatic duct (*ductus endolymphaticus*) and its dilated blind terminal end is called **sacculus endolymphaticus** . The endolymphatic duct passes through a bony canal (aqueduct of vestibule) in the posterior part of petrous temporal bone and its dilated terminal end projects on the posterior surface of petrous temporal bone beneath the dura mater of the posterior cranial fossa. The endolymph is absorbed by the epithelial cells lining the sacculus and drains into extradural

vascular plexus.

The utricle receives three semicircular ducts posteriorly through five openings.

### **Semicircular ducts**

The three semicircular ducts – anterior, posterior, and lateral – lie within the corresponding semicircular canals. They open into the utricle by five openings.

Each duct has one dilated end called **ampulla** . It corresponds to the ampulla of the corresponding semicircular canal. The ampullary end of each duct bears a raised crest (crista ampullaris), which projects into its lumen.

Peripheral receptors in saccule, utricle, and semicircular ducts (vestibular system) are as follows:

1. **Maculae:** These are sensory receptors located in the medial walls of saccule and utricle. They sense position of head in response to gravity and linear acceleration, that is *static balance* .
2. **Cristae:** These are sensory receptors located in the ampullated ends of the three semicircular ducts. They respond to angular acceleration, that is *kinetic balance* .

### **Innervation of peripheral receptors of vestibular system**

The vestibular or Scarpa's ganglion is situated in the lateral part of the internal acoustic meatus. It consists of bipolar neurons. The peripheral processes of these cells innervate hair cells of cristae and maculae, whereas their central processes aggregate to form the vestibular nerve.

### **Bony labyrinth**

The bony labyrinth consists of a series of intercommunicating bony cavities and canals within the petrous part of the temporal bone.

### **Parts**

The bony labyrinth presents three parts ([Fig. 18.17](#) ); from before backwards, these are as follows:

1. Cochlea
2. Vestibule
3. Semicircular canals (three)

**FIG. 18.17** ■ Diagrammatic representation of the cochlear duct within cochlear canal. Note that cochlear duct is filled with endolymph and scala vestibuli and scala tympani are filled with perilymph. CSF, cerebrospinal fluid.

## Cochlea

The cochlea resembles the shell of a common snail. Its apex (cupula) is directed towards the medial wall of the tympanic cavity, whereas its base is directed towards the bottom of the internal acoustic meatus.

The cochlea consists of a central pillar called modiolus, and a bony cochlear canal:

1. **Modiolus** is the axial bony stem around which the cochlear canal spirals. It is like an elongated cone. The base of modiolus lies at the fundus of the internal acoustic meatus and apex points towards the middle ear. The apex of the modiolus is overlaid by the apical turn of the cochlear canal. The modiolus is perforated spirally at its base in the internal acoustic meatus by the fibres of the cochlear nerve.

2. **Cochlear canal** is arranged spirally around the modiolus and makes two and three-fourth turns. Its basal turn bulges into tympanic cavity as the *promontory* .

A spiral ridge of bone called **spiral lamina** projects from the surface of the modiolus into the cochlear canal like a thread of a screw. The free edge of lamina splits into the upper and lower lips. The vestibular membrane extends from the upper lip of lamina to the outer wall of the cochlea, whereas basilar membrane extends from the lower lip of the lamina to the outer wall of the cochlea. The triangular area thus enclosed by the vestibular and basilar membranes, and the outer wall of the cochlear canal forms the **cochlear duct (scala media)** . The spiral lamina partly divides the cochlear canal into scala vestibuli above and scala tympani below. The scala vestibuli and scala tympani communicate with each other at the apex of the cochlea by a small opening called **helicotrema** (Fig. 18.16 ).

At the basal turn of cochlea, the scala vestibuli communicates with the anterior wall of the vestibule. Close to the basal turn of cochlea, scala tympani presents two features – fenestra cochleae and beginning of the aqueduct of cochlea:

1. The **fenestra cochleae** open into the tympanic cavity below and behind the promontory. It is closed by secondary tympanic membrane in life.
2. The **aqueduct of cochlea** is a narrow tubular canal through which perilymph within the cochlea communicates with the cerebrospinal fluid (CSF) of the subarachnoid space through cochlear canaliculus.

## Vestibule

The vestibule is a central ovoid cavity of bony labyrinth between cochlea in front and three semicircular canals behind. It lies medial to the middle ear cavity.

The **lateral wall** of the vestibule communicates with the middle ear cavity by **fenestra vestibuli** , which in life is closed by footplate of stapes and annular ligament.

The **medial wall** of the vestibule presents two recesses (Fig. 18.18 ): a **spherical recess** in front and an **elliptical recess** behind. The two recesses are separated by the vestibular crest, which splits inferiorly to enclose the cochlear recess. The spherical recess lodges saccule and is perforated by foramina for the passage of lower division of the vestibular nerve. The

elliptical recess lodges the utricle, and is perforated by foramina for the passage of the upper division of the vestibular nerve.

**FIG. 18.18** ■ Schematic interior of the bony labyrinth showing features in the medial, posterior, and anterior walls of the vestibule.

Just below the elliptical recess, there is an opening of a bony canal called **aqueduct of vestibule**, which reaches the epidural space on the posterior surface of the petrous temporal bone. The aqueduct of vestibule transmits tubular prolongation of membranous labyrinth, the **saccus** and **ductus endolymphaticus**. The **anterior wall** of the vestibule bears an opening, which communicates with scala vestibuli of the cochlear canal. The **posterior wall** of the vestibule bears five openings of three semicircular canals.

### Semicircular canals

There are three bony semicircular canals: anterior (superior), posterior, and

lateral. They lie in three planes at right angles to each other (Fig. 18.19). Each canal is approximately two-third of a circle and is dilated at one end to form the **ampulla** :

1. The **anterior semicircular canal** lies in a vertical plane at right angle to the long axis of the petrous temporal bone. It is convex upwards and its position is indicated on the anterior surface of the petrous temporal bone as **arcuate eminence** . Its anterior ampullated end communicates with vestibule anterolaterally. Its posterior non-ampullated end unites with the upper non-ampullated end of the posterior semicircular canal to form **crus commune** , which opens into vestibule.
2. The **posterior semicircular canal** also lies in a vertical plane parallel to the long axis of petrous temporal bone. Its convexity is directed backwards. Its lower ampullated end communicates with the vestibule and is innervated separately by a branch of vestibular nerve, which passes through *foramen singulare* in the fundus of internal acoustic meatus.
3. The **lateral semicircular canal** lies in the horizontal plane. Its convexity is directed posterolaterally. Its anterolateral end is ampullated and lies close to the ampullated end of the anterior semicircular canal. Both the ends of this canal open directly into the vestibule.

**FIG. 18.19** ■ Direction of semicircular canals.

Thus, three semicircular canals open in the vestibule by five openings.

### N.B.

- The *lateral semicircular canals* of two sides lie in the same plane.
- The *anterior semicircular canal* of one side lies parallel to the *posterior semicircular canal* of the other side.
- The *anterior and posterior semicircular canals*, lying across and along the long axis of the petrous temporal bone, are each at 45 degrees with the sagittal plane.

### Golden Facts to Remember

• <b>Largest piece of yellow elastic cartilage in the body</b>	Cartilage of the pinna/auricle of the external ear
• <b>Narrowest part of external auditory meatus</b>	Isthmus (4 mm lateral to tympanic membrane)
• <b>All parts of the ear acquire an almost adult size at birth except</b>	External ear
• <b>Safest quadrant of tympanic membrane for surgical incision (myringotomy)</b>	Posterior inferior quadrant
• <b>Smallest skeletal muscle in the body</b>	Stapedius
• <b>Point of maximum convexity on the medial surface of tympanic membrane</b>	Umbo
• <b>Smallest ball and socket joint in the body</b>	Incudostapedial joint
• <b>Smallest saddle joint in the body</b>	Incudomalleolar joint
• <b>All contents within the middle ear are outside its mucous lining except</b>	Air
• <b>Smallest long bone in the body</b>	Malleus
• <b>Smallest bone in the body</b>	Stapes
• <b>Widest part of the pharyngotympanic tube</b>	Pharyngeal end (1.25 cm behind the inferior nasal

	concha)
• <b>Age at which the foetus can hear outside conversation</b>	At 20th week of gestation of intrauterine life*
• <b>Parts of the ear and related structures, which are of full adult size at birth</b>	Tympanic cavity, ear ossicles, internal ear of mastoid antrum

\* This fact probably explains how *Abhimanyu* , who still inside the womb of his mother (Subhadra), could hear conversation between his mother and father (Arjuna), in the legend narrated in the great Indian epic, the *Mahabharata* , written thousands of years ago.

## CLINICAL CASE STUDY

A 10-year-old boy was taken by his mother to an ENT surgeon and complained that her son was suffering from earache. On otoscopic examination, the surgeon found that right external acoustic meatus of the boy was full of wax. He told the mother that her son had wax in his right ear and it had to be removed by a minor procedure called syringing, for which she agreed. While syringing, the child started coughing, gagging, and subsequently vomited. The pulse rate of the child decreased. He was diagnosed as a case of **earwax blockage** .

### Questions

1. Which glands in the external auditory meatus secrete wax?
2. Which nerves provide sensory innervation to the external auditory meatus?
3. Mention the anatomical basis of coughing, gagging, vomiting, and decreased pulse rate during syringing of the ear.

### Answers

1. Ceruminous glands (modified sweat glands). They secrete waxy oil called *cerumen* .
2. Auriculotemporal nerve, auricular branch of vagus.
3. Irritation of auricular branch of vagus during syringing may reflexly produce coughing (called ear cough), vomiting, and decrease in pulse rate.

---

# Chapter 19: Orbit and eyeball

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the boundaries and contents of orbit.
- Describe the extraocular muscles under the following heads: (a) origin, (b) insertion, (c) nerve supply, (d) actions, and (e) applied anatomy. **AN 31.1**
- Describe the nerves and vessels in the orbit. **AN 31.2**
- Write short notes on: (a) fascia bulbi (Tenon's capsule), (b) ciliary ganglion, (c) ophthalmic artery, (d) retinal detachment.
- Draw the labelled diagrams to show: (a) horizontal section of eyeball and (b) fundus of eye.
- Describe the parts and layers of eyeball. **AN 41.1**
- Give the anatomical basis of cataract, glaucoma, and sudden blindness (central retinal artery occlusion). **AN 41.2**
- Describe the position, nerve supply, and actions of intraocular muscles. **AN 41.3**
- Describe and draw the microanatomical features of cornea and retina. **AN 43.2**

## Orbit

The orbits are a pair of pyramidal-shaped bony cavities, located one on either side of the root of the nose and provides sockets for rotatory movements of the eyeballs. Each orbit is a four-sided pyramid with apex directed behind at the optic canal and base forward, represented by the orbital margin. The medial walls of two orbits are parallel to each other but lateral walls are set at

right angle to each other (Fig. 19.1 ).

**FIG. 19.1** ■ Diagrammatic horizontal section through orbits showing: angle formed between lateral walls, distance between medial walls and their direction (parallel to each other), visual and orbital axes.

The long axis of each orbit (**orbital axis** ) passes backwards and medially.

## Boundaries

The boundaries of the orbit (Fig. 19.2 ) are as follows:

**Medial wall (thinnest):** Formed by four bones; from before backwards, these are as follows:

1. Frontal process of maxilla
2. Lacrimal bone
3. Orbital plate of ethmoid
4. Body of sphenoid

**Lateral wall (strongest):** Formed by two bones, namely

1. Orbital surface of the zygomatic bone in front
2. Orbital surface of greater wing of sphenoid behind

**Floor:** Formed by three bones, namely

1. Orbital surface of the body of maxilla
2. Orbital surface of the zygomatic bone, anterolaterally
3. Orbital process of the palatine bone, posteromedially

**Roof:** Formed by two bones, namely

1. Orbital plate of the frontal bone in front
2. Lesser wing of the sphenoid behind.

A

B

**FIG. 19.2 ■ Orbit. ( A ) Margins and walls. ( B )**  
Schematic diagram to show the bones forming the walls of  
the orbit. P= Palatine bone, M= maxilla.

**Presenting features in four boundary walls of orbit (Fig. 19.3 )**

*Medial wall:* Presents two features which are as follows:

1. Lacrimal fossa is bounded in front by the anterior lacrimal crest of maxilla and behind by the posterior lacrimal crest of the lacrimal bone. The lacrimal fossa communicates with the nasal cavity through nasolacrimal canal. The lacrimal fossa and nasolacrimal canal lodge lacrimal sac and nasolacrimal duct, respectively.
2. Anterior and posterior ethmoidal foramina lie at the junction between medial wall and the roof of the orbit.

*Lateral wall:* Presents two features, namely

1. Zygomatic foramen. Sometimes, there are two small foramina, for zygomaticofacial and zygomaticotemporal nerves.
2. Whitnall's tubercle, a small bony tubercle just behind the lateral orbital margin and slightly below the frontozygomatic suture.

*Floor:* Presents two features, namely

1. Infraorbital groove and canal
2. Small rough impression in anteromedial angle for origin of inferior oblique muscle

*Roof:* Presents three features, namely

1. Fossa for lacrimal gland in the anterolateral part
2. Trochlear notch or spine at the anteromedial angle
3. Optic canal at the extreme posterior part of the roof

*Apex:* Lies at the posterior end of the orbit and is formed by sphenoid.

More precisely, it is formed by the centre of the bony bridge between optic canal and superior orbital fissure.

*Base:* Open and quadrangular, its boundaries form the orbital margins.

**FIG. 19.3** ■ Presenting features in the four boundary walls of the orbit.

## Orbital margins

The orbital margins are formed as follows:

1. **Supraorbital margin** is formed by the frontal bone and presents a notch – supraorbital notch or foramen – at the junction of its lateral two-third and medial one-third.
2. **Infraorbital margin** is formed by the zygomatic bone laterally and maxilla medially; it is continuous with *anterior lacrimal crest* medially.
3. **Medial orbital margin** is ill-defined. It is formed by the frontal bone above and lacrimal crest of the frontal process of maxilla below.
4. **Lateral orbital margin** is formed by zygomatic process of the frontal bone above and frontal process of the zygomatic bone below.

The margins of the orbit are readily palpable in vivo.

## N.B.

The orbital margins provide a fair bony protection to the eye except at the lateral margin. For this reason, protective eye guards are designed to

compensate for it in squash and handball players and still permitting good peripheral vision.

## Relations

The relations of orbit are as follows:

<i>Above</i>	Anterior cranial fossa and frontal air sinus (usually)
<i>Lateral</i>	Temporal fossa in front and middle cranial fossa behind
<i>Below</i>	Maxillary air sinus
<i>Medial</i>	Ethmoidal air sinuses.

## Orbital fascia or periorbita

It is the periosteum of the bony orbit, which lines the bony boundaries of the orbit and forms a funnel-shaped fascial sheath that encloses the orbital contents (Fig. 19.4 ). It is loosely attached to the bones; hence, it can be easily stripped off especially from roof and medial wall of the orbit.

### **FIG. 19.4 ■** Periorbita on roof of orbit.

At the optic canal and superior orbital fissure, it becomes continuous with the periosteum lining the interior of the skull (*endocranium*) . At the infraorbital fissure and orbital margins, it becomes continuous with the periosteum covering the external surface of the skull (*periosteum*) .

## **Contents**

Contents of the orbit include the following structures ([Fig. 19.5](#) ):

1. Eyeball (most important content)
2. Muscles
3. Fascia bulbi
4. Nerves
  - (a) Optic
  - (b) Oculomotor
  - (c) Trochlear
  - (d) Abducent
  - (e) Ophthalmic
  - (f) Ciliary ganglion
5. Ophthalmic artery
6. Ophthalmic veins
7. Lacrimal gland
8. Orbital fat.

**FIG. 19.5** ■ Sagittal section of the orbital cavity showing some of its contents.

### N.B.

All these structures lie within the orbital periosteum that lines the bony walls of the orbit except the:

- **Infraorbital nerve and vessels, and zygomatic nerve** lie outside the orbital periosteum, hence not included in the contents of the orbit.
- There are no oblique lymph vessels and lymph nodes in the orbit.

## Extraocular muscles of orbit AN 31.1

The extraocular muscles are classified into two groups: voluntary and involuntary.

### Voluntary muscles

There are seven voluntary muscles in the orbit. Of these, six muscles move the eyeball and one muscle moves the upper eyelid.

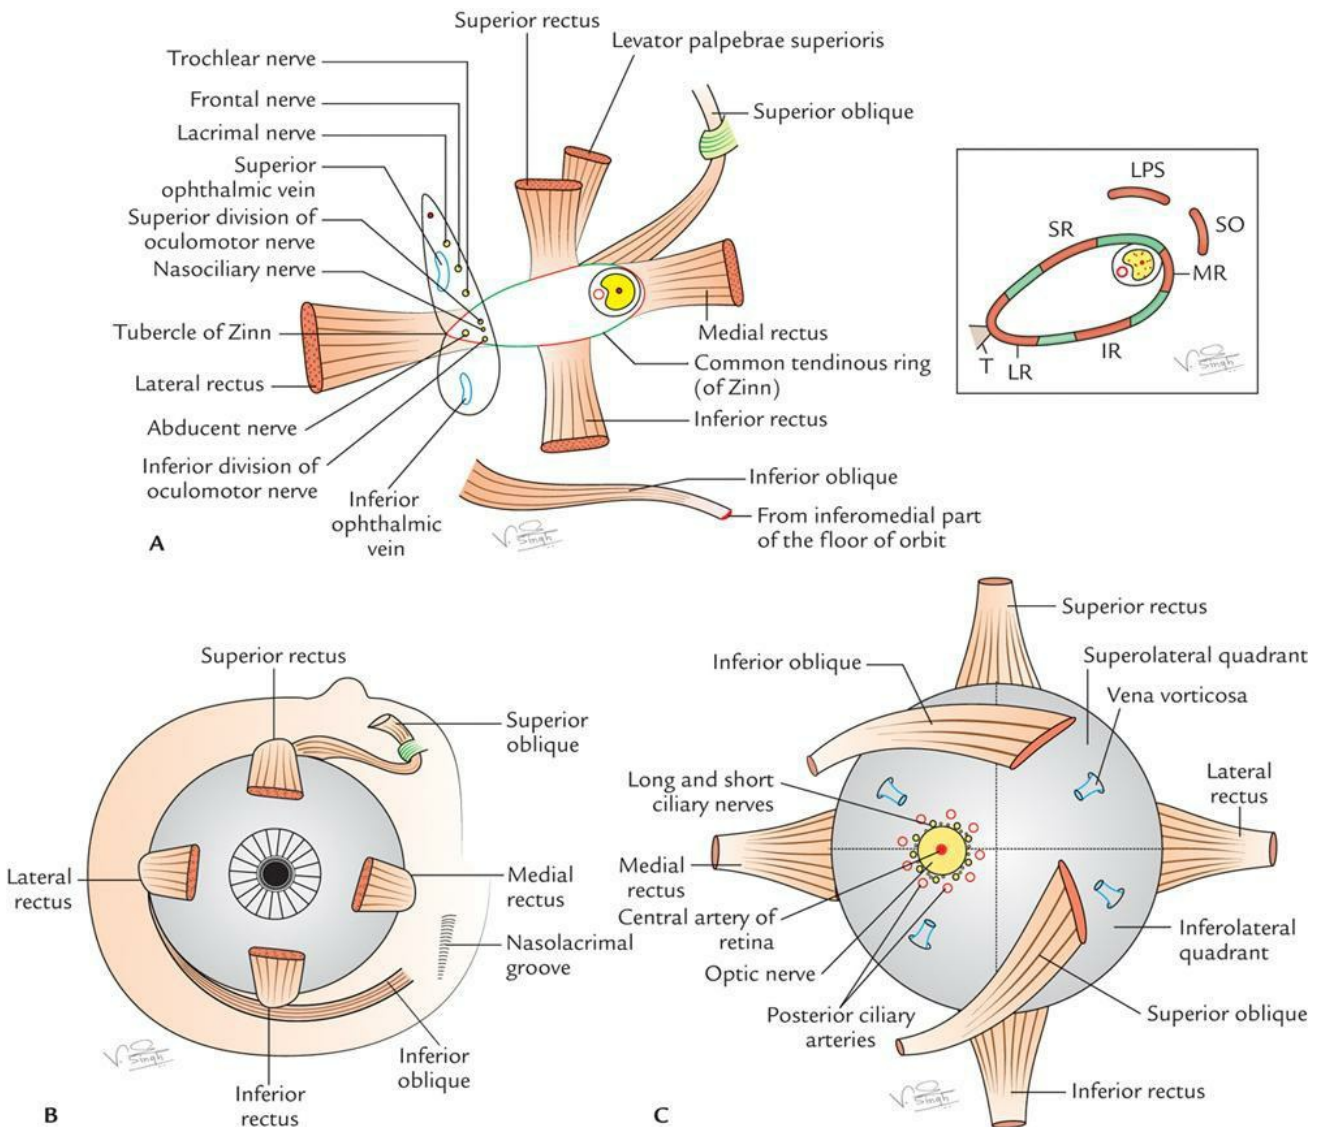

The **muscles moving the eyeball** are *four recti and two oblique muscles*.

1. Four recti muscles

- (a) Superior rectus
- (b) Inferior rectus
- (c) Medial rectus
- (d) Lateral rectus
2. Two oblique muscles
  - (a) Superior oblique
  - (b) Inferior oblique
3. One levator palpebrae superioris.

*The one, which moves the upper eyelid is called levator palpebrae superioris (Fig. 19.6)*

**FIG. 19.6 ■ Extraocular muscles. ( A ) Origin of voluntary extraocular muscle. The figure in the inset on**

the right side summarizes the origin of LPS, levator palpebrae superioris; SO, superior oblique; SR, superior rectus; IR, inferior rectus; MR, medial rectus; LR, lateral rectus; T, tubercle of Zinn. ( **B** ) Insertion of the recti muscles. ( **C** ) Insertion of the oblique muscles.

## Involuntary muscles

There are three involuntary/smooth muscles, namely *superior tarsal* or *Muller's muscle*, *inferior tarsal* and *orbitalis* . Their function is beyond the scope of this book.

The voluntary muscles are described in detail because of their functional significance in the following text.

## Recti muscles

### Origin

All the recti muscles arise in the back of orbit from the corresponding margins of the common tendinous ring. The lateral rectus arises by two heads (Fig. 19.6 A).

The **common tendinous ring** encloses the optic canal and middle part of the superior orbital fissure. It is attached medially to apex of the orbit and laterally to a small tubercle (**tubercle of Zinn** ) on the lower border of superior orbital fissure.

### Insertion

All the recti muscles are inserted into sclera little posterior to the limbus (corneoscleral junction) in front of the equator of the eyeball (Fig. 19.6 B). Average distance from limbus is as follows:

Medial rectus: 5 mm  
Inferior rectus: 6 mm  
Lateral rectus: 7 mm  
Superior rectus: 8 mm.

## Oblique muscles

The oblique muscles of the orbit are superior and inferior.

## 1. Superior oblique (fusiform muscle)

- Origin* – from body of sphenoid superomedial to the optic canal.
- Insertion* – into sclera behind the equator superolateral part of the sclera in posterior quadrant of the eyeball, between the superior and lateral recti (Fig. 19.6 C). The tendon of superior oblique muscle passes through a fibrocartilaginous pulley attached to the trochlear notch in the anteromedial part of the roof of the orbit.

## 2. Inferior oblique

- Origin* – from rough impression in the anteromedial angle of the floor of orbit, lateral to the lacrimal groove.
- Insertion* – into sclera behind the equator in the inferolateral part of posterior quadrant of the eyeball a little below and posterior to the insertion of superior oblique (Fig. 19.6 C).
- Nerve supply of voluntary muscles*** (Fig. 19.7 ): All the extraocular muscles that move the eyeball are supplied by the oculomotor nerve (3rd cranial nerve) except lateral rectus and superior oblique, which are supplied by the abducent nerve (6th cranial nerve) and trochlear nerve, respectively (*mnemonic* : LR6, SO4, i.e., LR [lateral rectus] by 6 CN and SO [superior oblique] by 4 CN).

**FIG. 19.7 ■** Nerve supply of the extraocular muscles.  
NC, nasociliary nerve.

### **Actions of extraocular muscles of eyeball**

The two eyes face forwards and their long axes (visual optical axes) lie in sagittal plane, parallel with each other and with medial walls of the orbits. The lateral walls of orbits slope backwards and medially making a right (90 degrees) angle with each other (see [Fig 19.1](#) ). The ocular muscles and optic nerve come from the apex of the orbit near the back of the medial wall and pass forwards and laterally to be attached to the eyeball. The actions of superior and inferior recti are, therefore, not straight, despite their name. The superior and inferior oblique muscles, therefore, have to act in concert with two recti in order to produce direct upward and downward movements of the eyeball.

### **Axis of movements of the eyeball**

- *Elevation and depression*: Around the transverse axis passing through the equator.
- *Adduction and abduction*: Around the vertical axis passing through the equator.
- *Rotation (torsion)*: Around the anteroposterior axis extending from anterior pole to posterior pole of the eyeball.

When 12-o'clock position of the cornea rotates medially, it is called **intorsion** and when it rotates laterally, it is called **extorsion** .

### **Actions of muscles moving the eyeball AN 43.5**

The actions of individual muscles are easily deduced from Starling's diagram ([Fig. 19.8](#) ).

**FIG. 19.8 ■** Schematic diagram (modified after Starling) showing actions of various extraocular muscles of eyeball. IO, inferior oblique; IR, inferior rectus; LR, lateral rectus; MR, medial rectus; SR, superior rectus; SO, superior oblique.

They are as follows:

**Superior rectus (SR):** Elevation, adduction, and intorsion

**Medial rectus (MR):** Adduction

**Inferior rectus (IR):** Depression, adduction, and extorsion

**Lateral rectus (LR):** Abduction

**Superior oblique (SO):** Depression, abduction, and intorsion

**Inferior oblique (IO):** Elevation, abduction, and extorsion.

### **N.B.**

*Associated movements of the eyeball:*

1. **Conjugate movements:** When both the eyes move in the same direction with visual axes being parallel.
2. **Disconjugate movements:** When the axes of both eyes converge or diverge.

## CLINICAL CORRELATION

**Strabismus/squint:** Unilateral paralysis of an individual muscle due to involvement of the nerves produces strabismus or squint (deviation of eye to the opposite side) and may result in diplopia (double vision). The strabismus is described in detail in [Chapter 22](#) , page 328, [Fig 22.7](#) .

In diplopia, the light from an object is not focused on the identical areas of both retinae. The real image falls on the macula of the unaffected eye and false image falls on the peripheral part of retina of the paralysed eye. The examples are as follows:

Muscle paralysed	Nerve involved	Effects
Lateral rectus	Abducent	Ipsilateral medial squint
Medial rectus	Oculomotor	Ipsilateral lateral squint
Superior oblique	Trochlear	Vertical squint

## Levator palpebrae superioris (LPS) muscle

### Origin

From undersurface of the lesser wing of sphenoid at the apex of the orbit, above the common tendinous ring by a narrow tendon.

### Insertion (see [Fig. 3.22](#) )

The muscle broadens as it passes forwards from its origin and divides into three lamellae:

1. Upper lamella consisting of skeletal muscle penetrates the orbital septum and passes through the fibres of orbicularis oculi to be inserted into the skin of upper eyelid.
2. Intermediate lamella consisting of smooth muscle (superior tarsal muscle) is inserted on to the upper border of the superior tarsal plate.
3. Lower lamella consisting of connective tissue is inserted on to the superior fornix of the conjunctiva.

### Nerve supply

1. Striped (skeletal muscle) part is supplied by the upper division of oculomotor nerve.
2. Unstriped (smooth muscle) part is supplied by the postganglionic

sympathetic fibres from the superior cervical ganglion.

## Actions

Elevation of the upper eyelid to open the eye.

## CLINICAL CORRELATION

**Paralysis of levator palpebrae superioris:** Paralysis of levator palpebrae superioris due to involvement of the oculomotor nerve leads to *complete ptosis* (drooping of upper eyelid). The lesion of cervical sympathetic chain (as in Horner syndrome) leads to *partial ptosis* (partial drooping of upper eyelid) as it affects only smooth muscle part of LPS.

## Fascia bulbi or fascial sheath of the eyeball

The fascia bulbi (**Tenon's capsule**) is a loose membranous sheath that envelops the eyeball and extends from optic nerve to the sclerocorneal junction. It is separated from the sclera by the episcleral space. The Tenon's capsule forms a socket for the eyeball to facilitate free ocular movements. It separates the eyeball from orbital fat ([Fig. 19.9](#)).

**FIG. 19.9 ■ Fascia bulbi (Tenon's capsule).**

The fascia bulbi is pierced by:

- (a) Tendons of four recti and two oblique muscles of the eyeball
- (b) Ciliary nerves and vessels around the entrance of the optic nerve.

### **Suspensory and check ligaments of the eye**

The fascia bulbi provides a tubular sleeve around each muscle that pierces it. From the fascial sleeve of lateral rectus, a triangular expansion (**lateral check ligament**) extends laterally for attachment to the lateral wall of the orbit on Whitnall's tubercle. Similarly, a triangular expansion from sleeve of medial rectus (**medial check ligament**) extends medially for attachment to the medial wall of the orbit on posterior lacrimal crest of the lacrimal bone.

The fascial sleeve of inferior rectus thickens on its underside and blends with the sleeve of inferior oblique as well as with the medial and lateral check ligaments forming a hammock-like support for the eyeball. It is called **suspensory ligament of the eye (or suspensory ligament of Lockwood)**. It is expanded in the centre and narrows at its extremities. At the posterior pole of the eyeball, the fascia bulbi becomes continuous with sheath of the optic nerve (Fig. 19.10).

**FIG. 19.10 ■** Suspensory and check ligaments of the eye. IO, Inferior oblique; IR, inferior rectus; LR, lateral rectus; MR, medial rectus.

## CLINICAL CORRELATION

- If suspensory ligament of the eye remains intact when the floor of the orbit is fractured or the maxilla is removed surgically, the eyeball does not sag.
- During enucleation of the eye, if Tenon's fascia is not damaged, and artificial eye is planted subsequently within the socket of Tenon's capsule, it is able to move.

## Nerves of the orbit AN 31.2

### Optic nerve

It has been described in detail in [Chapter 22](#) . Therefore, only brief account is presented here.

This nerve of sight is 4 cm long. It is made up of approximately 1 million myelinated nerve fibres. The optic nerve emerges from the eyeball, 3 or 4 mm nasal to the posterior pole of the eyeball. It runs backwards and medially, passes through the optic canal to enter the cranial cavity where it joins the optic chiasma. The entire nerve is enclosed in three meningeal sheaths derived from the meninges of the brain. The subarachnoid space around the brain, therefore, extends around the nerve up to the eyeball.

### Relations

The central artery and vein of the retina pierce the optic nerve inferomedially approximately 1.25 cm behind the eyeball. The optic nerve is crossed superiorly from before backward by ([Fig 9.13](#) ):

- Superior ophthalmic Vein
- Ophthalmic Artery
- Nasociliary Nerve

◦*Mnemonic: VAN.*

## Oculomotor nerve (Fig. 19.11 )

The two divisions of oculomotor nerve enter the orbit through superior orbital fissure within the common tendinous ring. Here the nasociliary nerve lies between the two divisions.

**FIG. 19.11** ■ Course and distribution of two divisions of the oculomotor nerves in the orbit. ( **A** ) Superior division. ( **B** ) Inferior division.

The **smaller superior division** runs forwards above the optic nerve and supplies the *superior rectus* , then pierces it to supply the *levator palpebrae superioris*.

The **larger inferior division** passes below the optic nerve and divides into three branches to supply *medial rectus*, *inferior rectus*, and *inferior oblique* .

The nerve to inferior oblique gives off the parasympathetic motor root to the ciliary ganglion.

## Trochlear nerve (Fig. 19.12 )

The trochlear nerve enters the orbit through the superior orbital fissure superolateral to the common tendinous ring and curves medially above the levator palpebrae superioris to reach deep to the posterior part of superior oblique, which it supplies.

**FIG. 19.12** ■ Course and distribution of the trochlear nerve in the orbit and also note the course of frontal and lacrimal nerves.

### Abducent nerve (**Fig. 19.13** )

The abducent nerve enters the orbit through superior orbital fissure within the common tendinous ring lateral to two divisions of the oculomotor nerve and nasociliary nerve, turns laterally away from optic nerve to enter the posterior part of lateral rectus.

**FIG. 19.13** ■ Course and distribution of the abducent nerve in the orbit and also note the course and branches of the nasociliary nerve. V= superior ophthalmic vein, A= ophthalmic artery, N= nasociliary nerve.

### Ophthalmic nerve (Fig. 19.14 )

The ophthalmic nerve is the first and the smallest of the three divisions of trigeminal nerve. It is purely sensory.

**FIG. 19.14 ■** Branches and distribution of the ophthalmic nerve.

### Course and relations

It arises from medial part of the convex anterior border of the trigeminal ganglion. It pierces the dura mater of the trigeminal cave and enters into the lateral wall of the cavernous sinus where it lies below the trochlear nerve. It enters the orbit through superior orbital fissure by dividing into three branches: lacrimal, frontal, and nasociliary.

### Branches and distribution

1. **Lacrimal nerve (smallest branch)** runs along the lateral wall of the orbit along with lacrimal artery and ends in the lacrimal gland (hence its name). It is joined by a communicating twig from the zygomaticotemporal branch of the maxillary nerve carrying postganglionic secretomotor fibres to the lacrimal gland. The lacrimal nerve supplies lacrimal gland and conjunctiva. Then it pierces orbital septum to supply the lateral part of the skin of upper eyelid.
2. **Frontal nerve (largest branch)** runs forwards between levator palpebrae superioris and periosteum lining the roof of the orbit. In the middle of orbit, it divides into large supraorbital and small supratrochlear nerves:
  - (a) *Supraorbital nerve* continues in the line of the frontal nerve to pass through supraorbital notch, where it turns upwards into the forehead and divides into medial and lateral branches, which supply the scalp as far back as the vertex.
  - (b) Supratrochlear nerve runs forwards medial to the supraorbital nerve. It passes above the trochlea for tendon of superior oblique muscle and then turns upwards along the superior orbital margin and supplies the skin of the lower part of the forehead.
3. **Nasociliary nerve** runs forwards and medially, crossing the optic nerve from above and from lateral to medial side behind the ophthalmic artery. On reaching the medial wall of the orbit, it ends by dividing into anterior ethmoidal and infratrochlear nerves.
  - It gives the following branches:
    - (a) **Sensory root to the ciliary ganglion** is given just before crossing the optic nerve.
    - (b) **Long ciliary nerves**, two or three, arise from nasociliary nerve as it crosses the optic nerve. They pass forward, enter the eyeball and supply sensory fibres to the ciliary body, iris, and cornea.

The long ciliary nerves also carry some postganglionic sympathetic fibres to the dilator pupillae.
    - (c) **Posterior ethmoidal nerve** enters the posterior ethmoidal foramen and supplies the ethmoidal and sphenoidal air sinuses.
    - (d) **Anterior ethmoidal nerve** enters the anterior ethmoidal foramen and then passes through anterior ethmoidal canal to reach the anterior cranial fossa. Now it runs forwards over

the cribriform plate of ethmoid and enters the nasal cavity by passing through a nasal slit at the side of crista galli. In the nasal cavity, the nerve lies in the groove on the posterior surface of the nasal bone and gives internal nasal branches to the nasal septum and lateral wall of the nose. At the lower border of the nasal bone, the nerve leaves the nasal cavity and appears on the dorsum of nose as *external nasal nerve*.

- (e) **Infratrochlear nerve** runs forwards on the medial wall of the orbit just below the trochlea and ends by supplying the skin of upper eyelid.

### Ciliary ganglion (Fig. 19.15 )

It is a peripheral parasympathetic ganglion, connected with the nasociliary nerve. Although topographically, it is connected to the nasociliary nerve from ophthalmic division of the trigeminal, but functionally it is connected to the oculomotor nerve.

**FIG. 19.15** ■ Roots and distribution of the ciliary ganglion. CN3= Third cranial nerve, CN5= fifth cranial

nerve, TG= trigeminal ganglion.

## Location

It is a minute body (2 mm in diameter) lying near the apex of orbit between the optic nerve and lateral rectus muscle.

## Roots

Three roots enter its posterior end. These are as follows:

1. **Motor (parasympathetic) root:** It is derived from nerve to inferior oblique and consists of preganglionic parasympathetic fibres from Edinger–Westphal nucleus. These fibres relay in the ganglion. The postganglionic parasympathetic fibres arise from the cells of the ganglion and pass through short ciliary nerves to supply the ciliary muscle and sphincter pupillae.
2. **Sensory root:** It is derived from nasociliary nerve. It consists of sensory fibres (for pain, touch, and temperature) from eyeball, which pass through the ciliary ganglion without relay.
3. **Sympathetic root:** It is derived from sympathetic plexus around internal carotid artery. It consists of postganglionic sympathetic fibres from superior cervical sympathetic ganglion. The fibres pass through the ganglion without relay and further pass through short ciliary nerves to supply the dilator pupillae and blood vessels of the eyeball.

## Branches

The branches of ciliary ganglion are **short ciliary nerves (8–10)**. They contain fibres from all the three roots, run above and below the optic nerve towards the eyeball. On reaching the eyeball, they pierce the sclera around the attachment of the optic nerve and pass forwards in the space between the sclera and choroid to reach the target organs.

## CLINICAL CORRELATION

**Interocular muscles are:** ciliary muscle, constrictor pupillae and dilator pupillae. They are responsible for accommodation of vision and supplied by ciliary ganglion. **AN 41.3**

**Infraorbital and zygomatic nerves (Fig. 19.16)**

They lie outside the periosteum of the orbit. They are described in detail in [Chapter 10](#) .

**FIG. 19.16** ■ Infraorbital and zygomatic nerves.

## Ophthalmic artery

It is a branch of internal carotid artery. It arises from internal carotid artery as it emerges from the roof of the cavernous sinus medial to anterior clinoid process close to the optic canal. The artery enters the orbit through optic canal inferolateral to the optic nerve, both lying in a common dural sheath ([Fig. 19.17](#) ).

**FIG. 19.17** ■ Ophthalmic artery.

The artery pierces the dura mater, ascends over the lateral side of the optic nerve to cross it superiorly from lateral to medial side along with the nasociliary nerve. It then runs forwards along the medial wall of the orbit tortuously to allow the movements of the eyeball. Near the medial angle of the eye, it terminates by dividing into two branches: **supratrochlear** and **dorsal nasal** .

### Branches

The branches of the ophthalmic artery are as follows:

1. **Central artery of the retina** (first and most important) arises from ophthalmic artery (still in dural sheath) below the optic nerve, runs forwards in the dural sheath and pierces the optic nerve

inferomedially approximately 1.25 cm behind the eyeball. The central artery reaches the optic disc through the central part of the nerve. It supplies the optic nerve and inner six to seven layers of the retina.

## CLINICAL CORRELATION

The **central artery of retina** is an example of a typical end artery. Its damage produces sudden total blindness on the side of the lesion.

2. **Lacrimal artery** arises from ophthalmic artery just before it crosses the optic nerve. It passes forwards along the upper border of lateral rectus and supplies the lacrimal gland, eyelids, and conjunctiva. The lacrimal artery gives off the following branches:
  - (a) Glandular branches to lacrimal gland
  - (b) Two lateral palpebral arteries – one to each eyelid
  - (c) Two zygomatic branches: zygomaticofacial and zygomaticotemporal
  - (d) Recurrent meningeal branch runs backwards to enter the middle cranial fossa through the superior orbital fissure
  - (e) Muscular branches.
3. **Posterior ciliary arteries** consist of two sets: long and short, both of which pierce the sclera of the eyeball around the optic nerve and chiefly supply the choroid and sclera. Long ciliary arteries are usually two and short ciliary arteries are usually seven in number. (Remember that *anterior ciliary arteries* arise from muscular arteries.)
4. **Supraorbital artery** accompanies the supraorbital nerve. It passes through supraorbital notch to enter the scalp and divides into medial and lateral branches.
5. **Posterior ethmoidal artery** enters the posterior ethmoidal foramen in the medial wall of the orbit and supplies the ethmoidal air sinuses, nasal cavity, and dura mater.
6. **Anterior ethmoidal artery** enters the anterior ethmoid foramen in the medial wall of the orbit and supplies the ethmoidal air sinuses, medial and lateral wall of nasal cavity, and dura mater.
7. **Dorsal (external) nasal artery** supplies the lower part of the dorsum of nose.
8. **Supratrochlear artery** accompanies the supratrochlear nerve to supply the forehead.

9. **Medial palpebral branches** , one to each eyelid, anastomose with the corresponding lateral palpebral branches of the lacrimal artery.

### **N.B.**

Branches of ophthalmic artery accompany all the branches of nasociliary frontal and lacrimal nerves (derived from ophthalmic nerve), and within the orbit supply all the extraocular muscles, lacrimal gland, and the eyeball.

## **Ophthalmic veins**

The ophthalmic veins drain the orbit and receive tributaries, which correspond to the branches of the ophthalmic artery ([Fig. 19.18](#) ). The ophthalmic veins are as follows:

1. **Superior ophthalmic vein:** It is a large vein and accompanies the ophthalmic artery. It commences above the medial palpebral ligament and runs backwards above the optic nerve along with the ophthalmic artery, passes through the superior orbital fissure to drain into cavernous sinus.
  - It communicates anteriorly at its commencement with the supraorbital and angular veins.
2. **Inferior ophthalmic vein:** It runs below the optic nerve and ends either by joining the superior ophthalmic vein or drains directly into the cavernous sinus.
  - It communicates with pterygoid venous plexus by small veins passing through the inferior orbital fissure.

**FIG. 19.18 ■ Ophthalmic veins.**

### **N.B.**

There are no lymphatics in the eyeball proper.

### **CLINICAL CORRELATION**

Because the ophthalmic veins drain into cavernous sinus and communicate with the extracranial veins, they act as routes through which infection can spread from outside to inside the cranial cavity.

### **Lacrimal gland**

It is a tubuloacinar type of exocrine gland, which secretes watery lacrimal fluid. It consists of two parts: orbital and palpebral. The orbital part is located in the lacrimal fossa on the anterolateral part of the roof of the orbit, whereas palpebral part is located in lateral part of the upper eyelid. Lacrimal gland has already been described in detail in [Chapter 3](#).

### **Orbital fat**

It fills up the space between the eyeball, optic nerve, and cone of four rectus

muscles. It serves as a cushion to stabilize the eyeball during its movements.

## **Eyeball (bulbus oculi) AN 41.1**

The eyeball (Latin, *oculus* ; Greek, *ophthalmos* ) or globe of the eye is an organ of sight and closely resembles a camera in its structure. It has light-sensitive retina and is provided with a lens system (cornea, lens, and refractive media) for focusing images and device for controlling the amount of light admitted (the iris diaphragm). Furthermore, like a camera, its inside is black to prevent reflection of light (Fig. 19.19 ).

**FIG. 19.19** ■ Horizontal section of the eyeball showing its internal structure including three coats and visual axis.

The eyeball is a highly durable structure for its wall enclosing the refractory media, is made up of three coats, and the fluid filled within it distributes hydraulic pressure uniformly to maintain its shape.

### Location

The eyeball occupies the anterior one-third of the orbital cavity and is embedded in the fat. It is enclosed in the thin fibrous sheath (Tenon's fascia), which separates the eyeball from the fat. The optic nerve emerges from it, a little medial to its posterior pole.

### Shape and size

It is almost spherical in shape and has a diameter of approximately 24 mm.

### Tunics/layers of the eyeball AN 41.1

The eyeball consists of three concentric coats ([Fig. 19.19](#)), namely

1. An **outer fibrous coat** consisting of sclera and cornea
2. A **middle vascular coat** consisting of choroid, ciliary body, and iris
3. An **inner nervous coat** consisting of the retina.

### Outer fibrous coat of the eyeball

#### Sclera

The sclera is the posterior five-sixth of the outer coat. It consists of dense fibrous tissue. It is opaque and a small portion of it is seen as the **white of the eye** in the palpebral fissure. The sclera is continuous anteriorly with the cornea. The junction between the sclera and cornea is termed **corneoscleral junction**. Just behind the corneoscleral junction, within the sclera is a circularly running canal called **sinus venosus sclerae (canal of Schlemm)**. Posterior to the canal is a triangular projection – the **scleral spur** – which points forwards and inwards and provides attachment to the ciliary muscle ([Fig. 19.20](#)). It is thinnest at the equator and thickest at the back, but weakest at the site of emergence of optic nerve.

**FIG. 19.20** ■ Meridional section of the eyeball showing ciliary region and the iridocorneal angle.

## Functions

1. Helps to maintain the shape of the eyeball
2. Protects internal structures
3. Provides attachment to muscles that move the eyeball.

## Structure piercing the sclera

1. **Optic nerve** pierces the sclera, a little inferomedial to the posterior pole of the eyeball. The perforating fibres of nerve make the area sieve-like (hence called *lamina cribrosa* ).
2. Posterior ciliary vessels and nerves around the optic nerve.
3. **Anterior ciliary arteries** pierce the sclera close to corneoscleral junction.
4. **Four choroidal veins** (also called *venae vorticosae*) pierce the sclera, just behind the equator.

## Cornea

The cornea is the transparent anterior one-sixth of the outer coat that allows the light to enter inside eyeball. It bulges forwards from the sclera at the *corneoscleral junction* called *limbus*. It is more convex than sclera because it

represents the segment of a smaller sphere. Its thickness is approximately 1 mm at the periphery and 0.5 mm at the centre.

## Features

1. It is avascular and nourished by permeation of nutrients from loops of capillaries at the limbus, aqueous humour, and lacrimal fluid.
2. It not only permits the light to enter the eye but also reflects the entering light.
3. It is highly sensitive and supplied by the ophthalmic division of trigeminal nerve.
4. The nerves of cornea form the afferent limb of the corneal reflex (closure of the eyelids on stimulation of the cornea).

## Microanatomical features AN 43.2

It consists of five layers; from outside inwards, these are as follows ([Fig. 19.21](#)):

1. **Corneal epithelium:** It consists of nonkeratinized stratified squamous epithelium.
2. **Anterior limiting membrane (or Bowman's membrane):** It is made up structureless homogenous mass without any elastic fibres.
3. **Substantia propria (corneal stroma):** It is made up of approximately 200–250 lamellae of fine collagen fibres, which cross each other at right angles to form corneal spaces.
  - Flattened fibroblasts are located between the lamellae.
  - The transparency of cornea is due to precise lattice arrangement of its lamellae embedded in the ground substance.
4. **Posterior limiting membrane/Descemet's membrane:** It is made up of structureless homogenous mass containing elastic fibres.
5. **Endothelium:** It consists of a single layer of low cuboidal cells.

**FIG. 19.21 ■** Layers of the cornea.

## CLINICAL CORRELATION

- **Arcus senilis:** The periphery of the cornea frequently displays a whitish ring in older persons, owing to fatty degeneration. This whitish ring is termed as *arcus senilis*.
- **Plastic contact lenses:** The central part of the cornea receives oxygen from the outside air. Therefore, the soft plastic contact lenses worn for long periods must be permeable to the air so that oxygen can reach the cornea.
- **Corneal opacity:** The normal cornea is transparent layer/membrane which allows the light to pass through it. The injury to cornea may cause opacity that may interfere with vision. The most common injuries of the eye are the cuts or tears of the cornea caused by foreign bodies. The corneal opacity does not allow the light to pass through it, hence impairs the vision.
- **Corneal graft:** The normal lack of vascularity and of lymph vessels accounts for the great success of *corneal grafts*. The cornea is successfully grafted from one person to the other.
- **Corneal reflex:** It is elicited clinically by gentle touching of the cornea with a wisp of cotton wool. As the cornea is touched both the eyes are closed.

**Pathway:** *Ophthalmic nerve* (afferent limb) □ Main sensory nucleus of trigeminal nerve □ Reticular formation □ Both the facial nerves (efferent limbs).

## Middle vascular coat of the eyeball

The middle coat is often called *vascular coat* because it contains most of the blood vessels of the eyeball. It is frequently known as **uveal tract** by the clinicians. This coat also contains a large number of melanin-containing cells. It consists of three parts; from behind forwards, these are choroid, ciliary body, and iris. These three parts together form **uvea** or **uveal tract**.

### Choroid

The choroid is the posterior part of the vascular coat of the eyeball. It is brown, thin, and highly vascular membrane lining the inner surface of the sclera. *Anteriorly*, it is connected to the iris by the ciliary body, and *posteriorly*, it is pierced by the optic nerve.

*Arteries:* They are derived from short ciliary arteries, which pierce the sclera around the optic nerve.

*Veins:* They are arranged in the form of whorls, which converge to form the four or five **venae vorticosae**, which pierce the sclera just behind the equator to open into the ophthalmic veins.

### N.B.

The inner surface of the choroid is firmly attached to the retina and nourishes the rods and cones of the retina by diffusion.

### Structure

It consists of four layers (from outside inwards), namely

1. **Suprachoroid lamina (lamina fusca):** It consists of loose network of elastic and collagen fibres and is traversed by long posterior ciliary vessels and nerves.
2. **Vascular lamina:** It consists of loose areolar tissue and pigment cells. It contains branches of short posterior ciliary arteries and veins, which converge in whorls to form four or five venae vorticosae, which pierce the sclera and drain into ophthalmic veins.
3. **Capillary lamina (capillary layer of choroid):** It consists of fine network of capillaries, which nourish photoreceptors of the retina (rods and cones) by diffusion.
4. **Basal lamina (membrane of Bruch):** It is a thin transparent membrane, which is firmly attached to the pigment cell layer of the

retina.

The last three layers form the choroid proper, which is separated from sclera by **suprachoroid lamina** .

### **N.B.**

In some animals such as cat, tiger and lion, the specialized cells of choroid form a reflective layer (reflecting media) called *tapetum*, which produces greenish glare in the eyes of these animals in the night.

## **Ciliary body**

The ciliary body is the thickening in the vascular tunic. It is continuous with the choroid behind and the iris in front. It is situated posterior to the corneoscleral junction in front of the ora serrata of the retina.

The ciliary bodies suspend the lens via suspensory ligaments.

### **Parts of the ciliary body**

The ciliary body is triangular in cross-section, thick in front and thin behind. The ciliary body consists of: (a) ciliary ring, (b) ciliary processes, and (c) ciliary muscle.

**Ciliary ring** is an outer fibrous ring, which is continuous with the choroid.

**Ciliary processes** are a group of 60- to 90-fold on the inner aspect of the ciliary body. They are arranged radially between the ciliary ring and the iris. The grooves between the processes provide attachment to the fibres of suspensory ligament of the lens.

◦The ciliary processes are a complex of capillaries and cuboidal epithelium, which secretes aqueous humour. The ciliary processes may be compared with choroidal plexus of the brain ventricles involved in the secretion of CSF.

**Ciliary muscle** is a small unstriated (smooth) muscle mass consisting of mainly two types of fibres, namely

1. Outer radial fibres
2. Inner circular fibres.

## **Functions**

Its main function is to focus the lens for near vision. The ciliary muscle as a whole acts as a sphincter; therefore, when its muscle fibres – both radial and

circular – contract, the choroid is pulled towards the lens reducing the tension on the suspensory ligaments. This allows the lens to assume a more spherical form because of its own elastic nature. Now lens can cause more refraction needed for accommodation.

## Iris

The iris is a contractile diaphragm between the cornea and the lens. An opening in its centre is called the **pupil**. The iris is attached at its periphery to the middle of the anterior surface of the ciliary body. Peripheral to this attachment, the ciliary body and narrow rim of sclera form the **iridocorneal angle**.

## Structure

The iris consists of four layers; from before backwards, these are as follows:

1. An anterior mesothelial lining
2. A connective tissue stroma containing pigment cells and blood vessels
3. A layer of smooth muscle, which consists of two parts:
  - (a) *Constrictor pupillae* – an inner (near the margin of the pupil) part made of circular fibres.
  - (b) *Dilator pupillae* – a peripheral part made up of radial fibres.

▲ **Nerve supply:** Constrictor pupillae is supplied by the parasympathetic fibres and dilator pupillae by the sympathetic fibres.

▲ **Actions:** The constrictor and dilator pupillae constrict and dilate the pupil, respectively.
4. A posterior layer of pigment cells, which is continuous with the ciliary part of the retina.

## Intraocular muscles of eye

These are ciliary muscle, dilator pupillae and constrictor pupillae.

The position, nerve supply and actions of these muscles are given in [Table 19.1](#).

**TABLE 19.1**

---

### Position, nerve supply, and actions of intraocular muscles

---

--

<b>Muscle</b>	<b>Position</b>	<b>Nerve supply</b>	<b>Actions</b>
1. Ciliary muscle	In ciliary body	Short ciliary nerve through ciliary ganglion (postganglionic parasympathetic fibres)	Relax suspensory ligament to make lens more convex for accommodation
2. Dilator pupillae radial smooth muscle fibre	In iris (peripheral part)	Short ciliary nerves (postganglionic sympathetic fibres)	Dilatation of pupil
3. Constrictor pupillae (circumferential ring of smooth muscle fibres)	In iris (inner part)	Short ciliary nerves through ciliary ganglion (postganglionic parasympathetic fibres)	Constriction of pupil during accommodation

### **Inner nervous coat of the eyeball (retina)**

The retina is the innermost coat of the eyeball ([Fig. 19.22](#)). It consists of two layers, namely

1. An outer pigment layer
2. An inner sensory layer.

The space between the two layers contains a gummy substance that glues the two layers.

**FIG. 19.22 ■** Ten layers of the retina.

The retina is present between the choroid and the hyaloid membrane of the vitreous. The retina diminishes in thickness from behind forwards. Anteriorly, it presents an irregular edge called **ora serrata**.

***From functional point of view, the details are as follows:***

1. The outer pigment layer consists of a single layer of irregular polygonal cells. The outer aspect of this layer is connected to Bruch's membrane and choroid while its inner aspect is connected to the photoreceptor cells.
2. The inner sensory layer of the retina is sensitive to light and is made up of three main layers of cells. From outside to inside these are:

- (a) Layer of photoreceptors cells called rods and cones.
- (b) A layer of bipolar neurons.
- (c) A layer of ganglion cells. The very thin noncellular continuation of the retina in front of the ora serrata covers the ciliary body and iris. Thus, the photosensitive part of the retina lines the inner surface of the eyeball posterior to the ciliary body. The nerve fibres arising from its ganglion cells cover inner surface and collect in the inferomedial region, where they pierce the outer two coats of eyeball and emerge as the optic nerve.

### Microanatomical features of retina AN 43.2

Histologically, the retina is composed of the following 10 layers:

1. Outer pigmented layer (pigmented cuboidal epithelium)
2. Layer of rods and cones (photoreceptor cells)
3. External limiting membrane (junctional complexes between Muller and photoreceptor cells)
4. Outer nuclear layer (cell bodies of rods and cones)
5. Outer plexiform layer (synapses between rods and cones; and bipolar neurons)
6. Inner nuclear layer (cell bodies of bipolar neurons)
7. Inner plexiform layer (synapses between bipolar and ganglion cells)
8. Ganglion cell layer (multipolar ganglion cells)
9. Nerve fibre layer (myelinated axons of ganglion cells)
10. Internal limiting membrane (Muller cells)

### Blood supply

The **deeper part of the retina**, that is up to the bipolar neurons is supplied by the central artery of the retina (a branch of the ophthalmic artery), whereas the **superficial part of the retina** up to the rods and cones is nourished by diffusion from the capillaries of the choroid.

### Venous drainage

It is by central vein of the retina, which drains into the cavernous sinus.

### Development of the retina (Fig. 19.23 )

The retina develops from a hollow outgrowth the **optic vesicle** from

diencephalon of primitive brain. The optic vesicle becomes invaginated to form the **optic cup**, consisting of two layers of cells. The outer layer differentiates to form the **pigment cell layer** and the inner layer differentiates to form the **neural layer**. The neural layer forms the remaining layers of the retina with photoreceptor cell (rods and cones) outermost, that is next to pigment cells. The ganglion cells are innermost. Therefore, light has to pass through them to stimulate the rods and cones.

**FIG. 19.23 ■** Stages in the development of the retina.

The two layers of optic cup remain separate during embryonic period but fuse later during early foetal period with potential space between the two. Therefore, in retinal detachment, the plane of cleavage is between pigment cell layer and neural layer.

### CLINICAL CORRELATION AN 41.2

- **Retinal detachment:** In retinal detachment, there is separation of two layers of the retina (i.e., pigment and neural layers).
- The outer pigment layer stays with choroidal layer, whereas inner photosensitive layer separates.
- **Appearance of the retina as seen through an ophthalmoscope:** The posterior region of retina (fundus) can be examined by an ophthalmoscope, a procedure called *fundoscopy* /ophthalmoscopic examination of fundus of eye.

The following features are observed (Fig. 19.24 ):

❧ (a) **Macula lutea**, a pale yellowish area near the posterior pole.

It is approximately 4 mm in diameter. A small pit (1.5 mm in diameter) in its centre is called *fovea centralis*, which is the point where light is normally focused.

◦(b) **Fovea**, is the portion of retina with maximum concentration of cone receptors; hence, the site of greatest visual acuity, that is, the ability to see the fine images (keenest vision).

◦(c) **Optic disc** (1.5 mm in diameter), a white spot approximately 3 mm medial to the macula. The depressed area in the centre is called *physiological cup*.

■ The nerve fibres from retina meet and pass through this region (optic disc) of the eyeball to form the optic nerve. The blood vessels of retina also pass through this spot.

■ Because there are no photoreceptor cells in the optic disc, it does not respond to the light. Therefore, the optic disc is also called *blind spot*.

◦(d) **Central artery of the retina** enters the eye through the centre of the optic disc. It divides into superior and inferior branches. Each of them further divides into temporal and nasal branches.

◦(e) **Retinal veins** follow the arteries. The branches of the central artery of retina are seen radiating over the edges of the optic disc. They are smaller and paler than veins. At points where they cross veins, the vein wall can be seen through the artery.

■ The normal optic disc appears as a cup-shaped area paler than the surrounding area (fundus). The edges of the disc are sharp and well defined.

■ The congestion of the optic disc from increased intracranial pressure is called *papilloedema* in which the optic cup is obscured and the disc margin is blurred.

**FIG. 19.24 ■** Features in the fundus of eye as seen during ophthalmoscopy. ( **A** ) Actual photograph. ( **B** ) Schematic diagram of fundus. (Source: Fig. 8.102, page 852, *Gray's Anatomy for Students* , Richard L Drake, Wayne Vogl, Adam WM Mitchell. Copyright Elsevier Inc. 2005, All rights reserved.)

### **N.B.**

The fovea centralis is the thinnest part of retina and its size is comparable to optic disc.

- **Occlusion of central retinal artery**

It is only artery to supply blood to retina. The occlusion of this artery causes sudden loss of eyesight in the eye on the side of lesion. **AN**

**41.2**

## **Arterial supply of the eyeball**

The eyeball is supplied by the following arteries ([Fig. 19.25](#)):

1. Central artery of the retina
2. Long and short posterior ciliary arteries
3. Anterior ciliary arteries

**FIG. 19.25** ■ Arterial supply of the eyeball.

In the region of ciliary body, a **major arterial circle** is formed by the anastomosis between long posterior ciliary artery and anterior ciliary artery. From major arterial circle, the vessel passes centripetally and anastomoses close to the pupillary margin to form the **minor arterial circle**.

## Compartments of the eyeball

The interior of the eyeball is divided into two compartments by the lens: a small anterior compartment in front of the lens and a large posterior compartment behind the lens (Fig. 19.26):

1. **Anterior compartment:** It is divided into two chambers: a smaller *anterior chamber* and a larger *posterior chamber*.
  - The anterior chamber lies between the iris and cornea and posterior

chamber between iris and lens. The two compartments communicate with each other through pupil.

- The two chambers are filled with an **aqueous humour**, which helps in maintaining the intraocular pressure. The aqueous humour is rich in ascorbic acid, glucose, and amino acids. It nourishes the cornea and the lens, which are otherwise avascular.
- Circulation of aqueous humour*: The aqueous humour is secreted in the posterior chamber by the ciliary processes. From here, it passes into the anterior chamber through the pupil. Here it passes through the spaces in the iridocorneal angle, located between the fibres of *ligamentum pectinatum* and then enter into the *canal of Schlemm*, from where it is drained by the *anterior ciliary veins*.

## CLINICAL CORRELATION

**Glaucoma: AN 41.2** If the drainage of aqueous humour is blocked, there occurs an abnormal increase in the intraocular pressure – a condition called *glaucoma*. As a result, there is severe pain in the eye due to pressure on the highly sensitive cornea.

The glaucoma may cause variety of visual problems, namely blindness due to compression of retina and its blood supply.

The intraocular pressure which normally is approximately 15 mm Hg can be measured on anaesthetized cornea (*tonometry*)

- 2. Posterior compartment:** It is behind the lens and much larger than the anterior compartment (comprising four-fifth of the eyeball). It is surrounded almost completely by the retina and is filled with colourless, transparent jelly-like substance called **vitreous humour/vitreous body**. The vitreous humour is enclosed in a delicate *hyaloid membrane*. Anteriorly, the hyaloid membrane forms a depression, the *hyaloid fossa* in which rests the lens. The vitreous humour helps in maintaining intraocular pressure and therefore the shape of the eyeball. Furthermore, it holds the lens and the retina in place. The *hyaloid canal* extends from optic disc to the lens. The canal marks the site of the *hyaloid artery* in the foetus. The hyaloid artery is a continuation of central artery of the retina, which disappears 6 weeks before birth.

**FIG. 19.26** ■ Compartments of the eyeball.

## Lens

The lens is an unusual biological structure. It is a transparent, biconvex body, 1 cm in diameter and 4 mm thick, placed between the anterior and posterior compartments of the eyeball.

## External features

The lens presents the following external features:

1. Anterior and posterior surfaces
2. Anterior and posterior poles
3. A circumference – the equator.

The line connecting the anterior and posterior poles is called the *axis of the lens*.

## Structure

The lens is enclosed in a transparent elastic capsule. Anteriorly deep to capsule lies capsular epithelium. In the centre, the epithelium is made up of a single layer of cuboidal cells. The cells at periphery elongate to give rise to lens fibres. These fibres get arranged concentrically and form the lens substance. The centre (nucleus) of the lens consists of oldest fibres. Here the lens fibres lose their nuclei and organelles. As a result, a special set of proteins called **crystallines** lie in the centre. The centre of the lens is, therefore, hard. The periphery of the lens (cortex) is soft because it is made up of more recently formed fibres.

## CLINICAL CORRELATION

- **Presbyopia (short vision):** The lens plays an important role in *accommodation*. The lens absorbs much of the ultraviolet light and becomes increasingly yellowish with age. It also becomes harder with age. As a result of which the power of accommodation is lessened in old age producing a clinical condition called *presbyopia*.
- **Cataract : AN 41.2** The opacity of the lens is termed *cataract*. With increasing age and in certain disease states, the lens becomes opaque. The increasing opacity leads to increasing visual impairment. This can be treated surgically by excision of opaque lens and replacement with an artificial lens.

## Suspensory ligaments of the lens (zonule of zinn)

The lens is suspended between anterior and posterior compartments of the eye by suspensory ligaments of the lens. These ligaments extend from ciliary body to the lens capsule mostly in front.

## Functions of the eye

The main function of the eye is focusing of light waves and stimulation of photoreceptors of the retina. This requires five basic processes, namely

1. Transmission of light waves through transparent media of the eyeball
2. Refraction (bending) of light waves through different refractive media of different densities
3. Accommodation of the lens to focus the light waves
4. Regulation of amount of light entering the eye through pupil by iris

- diaphragm
5. Convergence of eyeballs.

The stimulation of photoreceptors of retina generates action potentials that are relayed through the optic pathways to the visual cortex of the brain, where image is formed. The visual impairment may result if any one or more of these processes fail to function properly.

## Refractive media of the eye

These include:

1. Cornea (very refractive but not adjustable)
2. Aqueous humour
3. Lens (refractive and adjustable)
4. Vitreous humour/vitreous body.

All these media together form the **refractive apparatus** of the eye.

### N.B.

Most of the refraction by eye takes place at the anterior surface of the cornea (not in the lens as generally thought).

### Golden Facts to Remember

• <b>Most important content of the orbit</b>	Eyeball
• <b>All structures within the orbit lie inside the orbital periosteum except</b>	Infraorbital nerve and vessels and zygomatic nerve, which lie outside the orbital periosteum
• <b>Only extraocular muscle supplied by trochlear nerve</b>	Superior oblique muscle
• <b>Longest and thinnest extraocular muscle</b>	Superior oblique
• <b>White of the eye</b>	Sclera
• <b>Uvea (or uveal tract)</b>	Consists of choroid, ciliary body, and iris
• <b>Weakest site of sclera</b>	Lamina cribrosa
• <b>Site of keenest vision in retina</b>	Fovea centralis

• <b>Blind spot of the retina</b>	Optic disc
• <b>Maximum refraction by the eye takes place at</b>	Anterior surface of the cornea
• <b>Most successful homotransplant (i.e., between the individuals of the same species)</b>	Corneal transplant
• <b>Most important branch of ophthalmic artery</b>	Central artery of the retina
• <b>All the extraocular muscles are supplied by the oculomotor nerve</b>	Lateral rectus (supplied by the abducent nerve) and superior oblique (supplied by the trochlear nerve)
• <b>Canal of Schlemm</b>	Circular vascular channel within sclera just behind the corneoscleral junction
• <b>Refractive apparatus of the eye consists of</b>	Cornea, aqueous humour, lens, and vitreous humour
• <b>Tenon's capsule</b>	Thin membranous sheath enclosing the eyeball
• <b>Most common of all eye operations</b>	Cataract extraction

## CLINICAL CASE STUDY

### Case I

A 66-year-old person visited his family physician and complained of headache and blurring of vision. He referred him to an ophthalmologist, who on ophthalmoscopic examination found papilloedema (oedema of optic discs) and congestion of retinal veins. CT scan of his head revealed a large intracranial tumour in the region of the posterior cranial fossa. He was diagnosed as a case of **papilloedema**.

### Questions

1. What is an optic disc?
2. Describe the development of optic nerve and retina.
3. How does intracranial tumour cause papilloedema?

### Answers

1. The optic disc is a white spot (or pink area) approximately 3 mm medial to the posterior pole of eye, seen on ophthalmoscopic examination. The nerve fibres from retina leave the eyeball at this site to become the optic nerve. This area is devoid of photoreceptor cells. The central artery of retina enters and tributaries of central vein of retina leave the eyeball through the centre of the optic disc. The region of optic disc does not respond to light because of absence of photoreceptor cells (rods and cones); hence, it is also called the **blind spot**.
2. The optic nerve and retina develop from optic stalk and optic cup, respectively. The optic stalk and optic cup are derived from diencephalon as hollow outgrowth. The optic nerve being derived from brain is surrounded by three meninges.
3. The optic nerve is surrounded by three meninges of the brain, up to its entry in the eyeball and the subarachnoid space filled with CSF is continuous with subarachnoid space around the brain. As a result, rise in intracranial pressure (and hence CSF pressure) due to intracranial tumour, the central vein of retina traversing the subarachnoid space around optic nerve is compressed. This leads to venous congestion and oedema of the optic disc called papilloedema.

## Case II

A 65-year-old woman with diabetic women visited an ophthalmologist and complained of appearance of many bits of small blackish colour debris (floaters), sudden flashes of light, and some loss of vision. After thorough investigation, she was diagnosed as a case of **retinal detachment**.

## Questions

1. What is the site of retinal detachment?
2. What is the commonest cause of retinal detachment?
3. Name the layers of retina.

## Answers

1. It is separation between inner and outer layer of retina (for details, see page 288, [Fig 19.23](#) ).
2. The commonest cause of retinal detachment is old age occurs due to shrinkage of vitreous humour which pulls and breaks the inner layer of retina and enters between its two layers.

3. Ten layers (for details, see page 287).

---

# Chapter 20: Vertebral canal and spinal cord

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the contents of vertebral canal. **AN 42.1**
- Describe the extent of spinal cord in child and adult with the clinical applications. **AN 57.2**
- Describe transverse section of spinal cord at mid-cervical and mid-thoracic level. **AN 57.3**
- Describe in brief: (a) pyramidal tract and effects of its lesions, (b) spinothalamic tracts and their clinical significance, and (c) vertebral venous plexus and its clinical significance.
- Enumerate the ascending and descending tracts of spinal cord. **AN 57.4**
- Describe the anatomical basis of syringomyelia. **AN 57.5**
- Write short notes on: (a) filum terminale, (b) ligamentum denticulatum, (c) lumbar puncture, and (d) enlargements of spinal cord.
- Draw the labelled diagram of transverse section of spinal cord at mid-cervical level showing main ascending and descending tracts.

## Vertebral canal

The vertebral canal is an elongated cavity inside the vertebral column. The vertebral column consists of 33 segments/vertebrae lying one above the other. They are grouped according to the body regions: 7 cervical, 12 thoracic, 5 lumbar, 5 sacral, and 4 coccygeal vertebrae. In general, each vertebra consists of two parts: a ventral **body** and a dorsal **neural arch**, which enclose between them the vertebral foramen (for details, refer book *General*

*Anatomy with Systemic Anatomy, Radiological Anatomy, Medical Genetics*, 4ed. by Vishram Singh, [Chapter 8](#) : Vertebral Column).

The vertebral canal is a collective name given to the whole series of vertebral foramina lying one above the other when the vertebrae are held together in the vertebral column.

In human body, both in vivo and in vitro, the vertebral canal is a smooth-walled space bounded anteriorly by vertebral bodies, intervertebral discs, and posterior longitudinal ligament; and posteriorly by the vertebral laminae and *ligamenta flava* . On each side, it is bounded by the pedicles of vertebrae with intervening large *intervertebral foramen*.

The **vertebral canal** is continuous above with the **cranial cavity** and below with the **sacral canal** . The latter is considered as the part of the vertebral canal.

## Contents of the vertebral canal AN 42.1

The vertebral canal contains spinal cord surrounded by its meninges. The bony wall of the canal is separated from the spinal meninges by the **epidural space** .

The contents of vertebral canal are summarized as follows:

1. Epidural space
2. Spinal meninges
3. Spinal cord with its nerve roots.

### Epidural space

The epidural space lies between the spinal dura and the periosteum lining the vertebral canal. It is filled with loose areolar tissue and semiliquid fat and contains: (a) **minute spinal arteries** and (b) a network of veins – the **internal vertebral venous plexus** ([Fig. 20.1](#) ). Epidural space is also traversed by dorsal and ventral spinal nerve roots.

**FIG. 20.1** ■ Schematic transection of the vertebral canal showing its contents.

## Spinal arteries

These are segmental arteries, which arise from ascending cervical and deep cervical arteries in the cervical region, posterior intercostal arteries in the thoracic region, lumbar arteries in the lumbar region, and lateral sacral arteries in the sacral region. They enter the vertebral canal through intervertebral foramina along the spinal nerve roots. They supply spinal cord, its nerve roots and meninges, and the surrounding bones and ligaments.

## Vertebral venous plexus

The ventral venous plexus is a network of valveless veins running along the entire length of the vertebral column. It consists of two main plexuses, viz. *internal vertebral venous plexus* and *external vertebral venous plexus* (Fig. 20.2). (also see Chapter 17, Fig 17.8, page 241 Vol II).

## Internal vertebral venous plexus (Fig. 20.2)

The internal vertebral venous plexus (Batson's plexus) is a valveless network of veins in the epidural space of the vertebral canal and extends throughout the length of the vertebral canal. These veins correspond to the dural venous sinuses within the cranial cavity and are continuous with them through the foramen magnum.

**FIG. 20.2 ■** Vertebral venous plexus.

The plexus is drained by four subordinate longitudinal channels: two posterior and two anterior.

The anterior part of plexus receives large **basivertebral veins** (main tributaries) draining the active red narrow within the bodies of the vertebrae and sends efferent intervertebral veins through intervertebral foramina to drain into **external vertebral venous plexus**, which in turn drains into **segmental veins**. The segmental veins are body wall veins, namely vertebral, posterior intercostal, lumbar, and lateral sacral veins.

Apart from draining venous blood from the vertebrae, the internal vertebral venous plexus receives veins from spinal meninges and spinal cord.

### **External vertebral venous plexus/Batson's plexus (Fig. 20.2 )**

The *external vertebral venous plexus* lies outside the vertebral column and consists of anterior vessels lying in front of vertebral bodies and posterior

vessels lying on the back of the vertebral arches. They form anterior and posterior parts of external vertebral venous plexus respectively. The anterior and posterior vessels communicate with each other and with the *internal vertebral venous plexus*. All these veins are devoid of valves.

### **N.B.**

The veins of internal and external venous plexuses and their connecting veins do not have valves in their lumen. Consequently, the blood flows within these veins in both directions.

### **CLINICAL CORRELATION**

#### **Role of internal vertebral venous plexus in metastasis of cancer:**

The *internal vertebral venous plexus* provides a venous bypass when the inferior vena cava fails to cope with sudden flush of blood resulting from sudden increase in intra-abdominal pressure as during coughing and straining. It transmits venous blood from areas of high venous pressure, for example, from the tributaries of inferior vena cava (lateral sacral and lumbar veins) to the tributaries of superior vena cava (posterior intercostal and vertebral veins).

*Thus, pelvic tumours, especially cancer prostate, can spread to vertebral bodies and even to skull without having to pass through heart and lungs and produce secondaries at these sites.*

## **Spinal meninges**

The spinal cord is surrounded by three coverings called *meninges* (Fig. 20.3). From superficial to deep, these are as follows:

1. Spinal dura mater
2. Spinal arachnoid mater
3. Spinal pia mater

**FIG. 20.3** ■ Schematic transverse section of the spinal cord showing meninges and formation of meningeal sheaths onto the spinal nerve roots.

The potential space between the dura and arachnoid maters is termed as **subdural space** , whereas the large space between the arachnoid mater and pia mater is known as **subarachnoid space** .

### Spinal dura mater

It is the prolongation of the inner meningeal layer of cranial dura mater and extends from foramen magnum to the lower border of S2 vertebra. It is attached firmly to the foramen magnum, the tectorial membrane, and the posterior longitudinal ligament on the body of axis vertebra. Elsewhere, it lies free in the vertebral canal. The lower blind end of dural tube is pierced by filum terminale in its centre.

The spinal dura mater is pierced segmentally by dorsal and ventral roots of the spinal nerves and prolonged over these roots as sleeve-like projections, which enter the intervertebral foramina and ends by fusing with the

epineurium of the spinal nerves. The recurrent meningeal branches of the spinal nerves supply the spinal dura.

### Subdural space

It is a potential space between the spinal dura and arachnoid mater containing a thin film of serous fluid, which acts as a lubricant. As a result, the dura mater can freely move over the arachnoid mater. The subdural space is prolonged to a short distance around the roots of the spinal nerves.

### Spinal arachnoid mater

It is a thin transparent vascular membrane that loosely invests the spinal cord. Above, it is continuous with the arachnoid mater surrounding the brain and below it extends up to the lower border of second sacral vertebra. It is separated from pia mater by the subarachnoid space. The arachnoid mater sends numerous delicate thread-like processes across the subarachnoid space to the pia mater forming a spider's web-like arrangement.

### Subarachnoid space

The subarachnoid space is a relatively large space between arachnoid mater and pia mater. It is filled with cerebrospinal fluid (CSF), which forms about half of the total volume of CSF (i.e., 75 ml out of 150 ml). It communicates with the subarachnoid space around the brain at the foramen magnum. Below the level of conus medullaris (lower conical end of spinal cord), the space is quite roomy (called **lumbar cistern**) and contains only cauda equina and filum terminale in a pool of CSF. The *lumbar puncture* is usually done in this region between L3 and L4 vertebra.

### Spinal pia mater

It is a vascular membrane that closely invests the spinal cord. The pia mater is modified at some places. These modifications are called **processes of pia mater**.

### Processes of pia mater

1. **Filum terminale:** It is a delicate thin thread-like prolongation of pia mater beyond the conus medullaris. It is approximately 20 cm long and extends from tip of conus medullaris to the base of the coccyx. It pierces the dural tube, passes through the sacral canal and sacral

hiatus to gain attachment on the dorsum of the first piece of the coccyx. The *filum terminale* is divided into two parts: **filum terminale internum** and **filum terminale externum**.

- The *filum terminale internum* is approximately 15 cm long and lies within the dural sac.
- The *filum terminale externum* is 5 cm long and lies outside the dura mater.

2. **Ligamenta denticulata:** On each side between dorsal and ventral nerve roots, the pia mater forms narrow ribbon-like transparent bands called **ligamenta denticulata**. The lateral margin of each *ligamentum denticulatum* sends 21 teeth-like projections, which pass through subarachnoid space and arachnoid mater to gain attachment on the inner surface of the dural tube between the points of emergence of two adjacent spinal nerves. Thus, *ligamenta denticulata* help to anchor the spinal cord in the middle of the subarachnoid space. The first tooth of *ligamentum denticulatum* is at the level of the foramen magnum, whereas the last tooth lies between T12 and L1 spinal nerves ([Fig. 20.4](#)).
3. **Linea splendens:** It is a thickened band of pia mater along the anterior median fissure of the spinal cord.
4. **Subarachnoid septum:** It is a fenestrated pial septum in the midsagittal plane, which connects the pia mater with arachnoid mater posteriorly. Posteriorly, the pia mater is also attached to the posterior median septum of the spinal cord.

**FIG. 20.4** ■ Posterior view of part of the spinal cord showing ligamenta denticulata.

## CLINICAL CORRELATION

- **Lumbar puncture ( Fig. 20.5 ):** AN 57.2 The lumbar puncture is done to draw CSF from subarachnoid space for diagnostic and therapeutic purposes. The needle is inserted between L3 and L4 or L4 and L5 vertebrae with patient's back flexed either in sitting position or lying on a bed in left lateral position, usually the later when patient is curled up lying on left side. The needle passes through the supraspinous and interspinous ligaments and between ligamenta flava before piercing the dura mater. As the dura mater is pierced, there is a distinct feel of *give way* . As the spinal cord ends at the lower border of L1 vertebra, there is no danger of damage to the spinal cord (for details, see *Clinical and Surgical Anatomy*, 2ed. by Vishram Singh).

In children spinal cord ends at the level of L3 vertebra. Hence lumbar puncture should be done at or below the L4 level.

- **Spinal anaesthesia:** To give spinal anaesthesia, the anaesthetic solution is injected into the subarachnoid space. It mixes up with CSF surrounding the spinal nerve roots which get anaesthetized. The procedure is same as that of lumbar puncture.
- **Epidural anaesthesia:** To give epidural anaesthesia, anaesthetic solution is injected into the epidural space at the desired site without piercing the dura mater. The solution infiltrates through the meningeal sheaths around the nerve roots, which consequently get anaesthetized.

**FIG. 20.5** ■ Lumbar puncture. Insertion of needle in the interspinous space between L3 and L4.

## Spinal cord

The spinal cord is the long (average length 45 cm) lower cylindrical part of the central nervous system occupying the upper two-thirds of the vertebral canal.

In adults, it begins at the upper border of C1 vertebra as the continuation of medulla oblongata and usually terminates opposite the *intervertebral disc between the L1 and L2* vertebrae.

In children, the spinal cord ends at the level of L3 vertebra.

*The functions of the spinal cord are as follows:*

1. Transmission of information to and fro between body and brain
2. Execution of simple reflexes.

### External features (Fig. 20.6 ) AN 57.1

The spinal cord is cylindrical structure, somewhat flattened anteroposteriorly. Its lower end tapers into a cone forming the **conus medullaris** . The spinal cord gives origin to 31 pairs of spinal nerves, i. e., 8 pairs of cervical, 12 pairs of thoracic, 5 pairs of lumbar, 5 pairs of sacral, and only 1 pair of coccygeal nerves.

**FIG. 20.6 ■** TS of spinal cord showing external features.

PLS= Posterolateral sulcus, ALS= anterolateral sulcus.

The girth of spinal cord increases considerably in the regions that give origin to large nerves of the upper and lower limbs. These enlargements are known as **cervical and lumbar swellings/enlargements of spinal cord**

The spinal cord presents the following external features:

1. Fissures and sulci
2. Attachments of spinal nerve roots
3. Enlargements of the spinal cord.

### **Fissures and sulci**

The anterior aspect of spinal cord possesses a deep midline groove called **anterior median fissure** . It extends along the entire length of the spinal cord. On either side of anterior median fissure, it presents anterolateral sulci. The posterior aspect of the spinal cord presents a shallow posterior median sulcus, from which a posterior median septum of neuroglial tissue extends into the substance of the cord to a variable extent ([Fig 20.7](#) ). (Refer *Gray's Anatomy for Students*, [Fig. 9.1](#) , page 1304.)

**FIG. 20.7 ■** Spinal cord and spinal nerves. *Source:* Courtesy: Gray's Anatomy for Students, 2nd edn, page

### Attachments of spinal nerve roots

The anterior and posterior roots of the spinal nerve unite within the intervertebral foramina. The anterior root is formed by three or four rootlets, which emerge along the anterolateral sulcus of the spinal cord. The posterior root is formed by several rootlets, which are attached to the **posterolateral sulcus** of the spinal cord. A short distance from the cord, the rootlets unite to form a single root. The anterior and posterior roots pass to their appropriate intervertebral foramina, where each evaginates dura mater separately before uniting to form the nerve trunk. The *ganglion* on the posterior root lies in the intervertebral foramen, within the tubular evagination of dura and arachnoid proximal to the point of union of anterior and posterior nerve roots.

At all levels from C1 to L1 vertebrae, anterior and posterior nerve roots pass in front of and behind the ligamentum denticulatum, respectively.

As the spinal cord is shorter than the vertebral canal, the course of spinal nerve roots in the vertebral canal to reach the appropriate intervertebral foramen varies.

The upper cervical nerve roots pass almost horizontally, the thoracic nerve roots pass obliquely, whereas lumbar and sacral nerve roots descend almost vertically downwards forming the *cauda equina*.

The cauda equina is a leash of lumbar (except L1), sacral and coccygeal nerve roots around the filum terminale in the pool of CSF. It is so named because the lower end of the spinal cord along with the aforementioned structures resembles the tail of a horse (cauda = tail, equina = horse).

### Exit of spinal nerves

All spinal nerves exit out of vertebral canal through an intervertebral foramina, except the following ones:

- C1 spinal nerve emerges above the posterior arch of atlas vertebra.
- C2 emerges between the posterior arch of atlas and axis vertebra.
- S5 and Cx1 emerge through lower end of the sacral canal. Other sacral nerves have separate sacral foramina for each ramus.

### Spinal ganglia

These are collection of nerve cell bodies of pseudounipolar neurons. The

nerve cell bodies give rise to sensory fibres (peripheral processes) in the peripheral nerve and nerve fibres (central processes) in the dorsal root on which the ganglion lies. There is no synapse in the spinal ganglia.

### **N.B.**

All the spinal ganglia lie in the intervertebral foramina except the sacral and coccygeal, which lie in the sacral canal and the first two cervical, which lie in the corresponding position above and below the first cervical vertebra, behind the articular facets.

## **Spinal segments**

The portion of spinal cord, which gives origin to a pair of spinal nerves, is termed as **spinal segment**. (The spinal segments are not visible on the surface.) There are 31 pairs of spinal nerve. Thus, the spinal cord consists of 31 spinal segments. The size of segment depends on the amount of tissue supplied by each segment.

Because of relative shortening of the spinal cord as compared to the vertebral canal, the spinal segments lie above their corresponding vertebral level, a fact of great clinical significance in determining the level of vertebral injury from signs and symptoms produced because of injury to a particular segment. [Table 20.1](#) provides the approximate vertebral levels of the spinal segments.

 **TABLE 20.1**

### **Approximate vertebral levels of the spinal segments**

<b>Spinal segments</b>	<b>Spinous levels of vertebrae</b>
Cervical 1–8	Foramen magnum to C6 vertebrae
Thoracic 1–6	C6–T4 vertebrae
Thoracic 7–12	T4–T9 vertebrae
Lumbar and sacral	T10–L1 vertebrae

## **Enlargements of spinal cord**

The spinal cord is not uniform in diameter. It presents two enlargements in those regions, which supply the muscles of upper and lower limbs. The two enlargements are as follows:

1. **Cervical enlargement:** In the region of C4–T1 spinal segments with maximum diameter of 38 mm at the level of C6 segment. The nerves arising from these segments form **brachial plexus**.
2. **Lumbar enlargement:** In the region of L1–S3 spinal segments with maximum diameter of 35 mm at the level of S1 segment. The nerves arising from these segments form the **lumbo-sacral plexus**.

The vertebral levels of these enlargements are quite different from that of spinal segments, namely cervical enlargement lies opposite C3–T1 vertebrae and lumbar enlargement lies opposite T9–L1 vertebrae.

These enlargements in spinal cord are due to greatly increased mass of motor cells in the anterior horns of grey matter in these spinal segments.

### Internal structure AN 57.3

It is studied by cutting transverse sections of spinal cord at various levels (Fig. 20.8).

**FIG. 20.8** ■ Cross-sections of the spinal cord in the cervical, thoracic, and lumbar regions. The shape of sections is given on the left side, whereas the shape of anterior and posterior horns is given on the right side.

The spinal cord consists of a central mass of grey matter made up of nerve cells and peripheral mass of white matter made up of fibre tracts.

In a cross-section of the cord, the grey matter is seen as an H-shaped (or butterfly shaped) fluted column, extending throughout the length of the spinal cord. It is divided into symmetrical right and left comma-shaped masses, which are connected across the midline by a **transverse grey commissure** . The central canal of the cord passes through the centre of the grey commissure. The canal is surrounded by **substantia gelatinosa centralis** . The lateral comma-shaped mass of grey matter is divided by a transverse grey commissure into a narrow elongated **posterior horn** and **broad anterior horn** . The posterior horn extends almost up to the surface of the cord but anterior horn falls short of it ([Fig. 20.7](#) ).

In the thoracic and upper two lumbar segments (T1–L2), a triangular projection juts out from the side of the lateral grey mass between the anterior and posterior horns, nearly opposite to the grey commissure. It is called the **lateral horn** . The posterior horns are connected to the surface by a gelatinous substance called **substantia gelatinosa** . The amount of grey matter and shape of its horns, and amount of white matter varies at different levels ([Fig. 20.8](#) ).

The anterior grey horns are largest in the cervical and lumbar enlargements as they are proportional to the volume of the tissue supplied by the spinal nerves at these levels. The posterior white columns are largest in the cervical region.

[Table 20.2](#) enumerates the characteristic features of the spinal segments in different regions of the spinal cord.

**TABLE 20.2**

---

**Characteristic features of the spinal segments as seen in transverse sections at cervical, thoracic, and lumbar regions of the spinal cord**

---

Features	Levels		
	Cervical	Thoracic	Lumbar
Grey matter	Large	Small	Large
Posterior horn	Slender and extends far	Slender	Bulbous

Anterior horn	posteriorly Massive	Slender	Bulbous
Lateral horn	Absent	Present	Present only in L1 and L2 segments; absent in L3, L4 segments
Reticular formation	Well developed	Poorly developed	Absent
Amount of white matter	Massive ++++	Large (less than in the cervical region) +++	Less (but slightly less than in the thoracic region) +++

## Grey matter

The grey matter of spinal cord consists of: (a) nerve cells, (b) neuroglia, and (c) blood vessels.

## Types of neurons in the grey matter

1. **Motor neurons:** These are present in the anterior and lateral horns.

◦ *Types of motor neurons in the anterior horn*

(a) *Alpha (α) neurons* : They are large multipolar cells (25 μm or more in diameter) and supply the extrafusal skeletal muscle fibres.

(b) *Gamma (γ) neurons* : They are small multipolar cells (15–25 μm in diameter) and supply the intrafusal muscle fibres of the neuromuscular spindles in skeletal muscles.

◦ *Types of motor neurons in the lateral horn*

▮ They are preganglionic autonomic neurons.

## N.B.

The axons of motor neurons leave the spinal cord as the final common path (Sherrington) through the ventral roots of the spinal nerves and reach the skeletal muscles.

2. **Sensory neurons:** These are present in the posterior horn and involved in relay of sensory information to the different parts of the brain forming **ascending tracts** ; or to the other segments of spinal cord forming **intersegmental tracts** .

3. **Interneurons:** These are small neurons present throughout the grey matter of the spinal cord. They connect different types of neurons, hence also called **association neurons**. These are either inhibitory or excitatory and concerned with integration of segmental activities.

## Nerve cell groups in the grey columns of spinal cord

### Cell groups in the anterior grey column

Numerous groups of motor neurons are found in the cross-section of anterior grey column, representing several longitudinally arranged columns of varying lengths. They are divided into three main groups or nuclei: (a) medial, (b) lateral, and (c) central.

**Medial group** extends along most of the length of the spinal cord and innervates the axial musculature of the neck and trunk. This is further subdivided into *ventromedial* and *dorsomedial* parts.

**Lateral group** is confined to the cervical and lumbosacral enlargements and supplies the limb muscles.

**Central group** forms three definite nuclei, which are fairly localized. These are as follows:

1. **Phrenic nucleus** in the cervical region (extending from C3 to C5 segments) innervates the diaphragm.
2. **Lumbosacral nucleus** in the lumbosacral region (extending from L2 to S3 segments). Its function is unknown so far.
3. **Spinal nucleus of accessory (11th cranial) nerve** in the cervical region (extending from C1 to C5 segments) and giving origin to the spinal root of accessory nerve.

### Cell groups in the posterior grey column

In the posterior grey column, the cell groups are arranged into four longitudinal columns; from the apex towards the base, they are as follows:

1. Marginal nucleus
2. Substantia gelatinosa (of Rolando)
3. Nucleus proprius
4. Nucleus dorsalis (or Clarke's column)
5. Visceral afferent nucleus.

**Marginal/posteromarginal nucleus**, is a layer of neurons which caps the posterior horn. It receives some incoming posterior root

fibres (mainly from tract of Lissauer) and relay information related to pain and temperature.

**Substantia gelatinosa** is situated at the apex of the posterior grey column and extends throughout the length of the spinal cord. It is composed of small neurons (also called *interneurons*). It receives the afferent fibres of the lateral division of the posterior nerve roots conveying primarily, the pain and temperature sensations. Some of these fibres synapse with the interneurons of substantia gelatinosa. The substantia gelatinosa is continuous above with the nucleus of spinal tract of the trigeminal nerve.

**Nucleus proprius** is a group of large nerve cells situated anterior to the substantia gelatinosa and constitutes the main bulk of cells present in the posterior grey column.

- It extends along the whole length of the spinal cord. It receives fibres from posterior root ganglia which carry sensory information such as light touch, pain and temperature.

**Nucleus dorsalis (Clarke's column)** occupies the medial part of the base of the posterior grey column, projecting somewhat into the posterior funiculus, and extends from C8 to L2/L3 segments of the cord and receives proprioceptive afferents (muscle and joint sense) and exteroceptive afferents (touch and pressure from the trunk and lower limb).

**Visceral afferent nucleus** is located lateral to the nucleus dorsalis and extends from T1 to L2 and from S2 to S4 segments of the cord and receives visceral afferents from the dorsal nerve roots.

### **Cell groups in the intermediate (lateral) grey column**

The cells of the lateral grey column form two nuclei: (a) intermediolateral and (b) intermediomedial.

The **intermediolateral nucleus** extends from T1 to L2 segments of the cord and gives origin to preganglionic fibres of the sympathetic nervous system (*thoracolumbar outflow*), which leave the cord along with the anterior nerve roots.

The **intermediomedial nucleus** extends from S2 to S4 segments of the cord and gives origin to preganglionic fibres of parasympathetic nervous system (*sacral outflow*), which also pass out through the anterior nerve roots of the corresponding sacral nerves.

### N.B.

Apart from the central grey matter, there are strands of grey matter in the lateral white column adjacent to the base of the posterior horn, which are termed *reticular formation*.

### White matter

The white matter of the spinal cord surrounds the central H-shaped mass of grey matter and mainly consists of nerve fibres, the large proportion of them being myelinated, giving it a white appearance.

In each half of the spinal cord, the white matter is divided into three parts called columns:

1. **Posterior white column** between the posterior median septum and the posterior horn.
2. **Lateral white column** between the anterior and posterior horns.
3. **Anterior white column** between the anterior median fissure and the anterior horn.

The anterior white columns are joined together by the **white commissure**.

Each white column is made up of tracts, which are either ascending (sensory) or descending (motor).

### N.B.

In general, the posterior white column is sensory, the anterior column is motor, and lateral column is mixed (i.e., motor as well as sensory). In general, the ascending tracts are located towards the periphery and the descending tracts towards the centre.

### Tracts of the spinal cord AN 57.4

The tracts are defined as collections of nerve fibres within the central nervous system, which have same origin, course, and termination. They are sometimes referred to as *fasciculi* (= bundles) or *lemnisci* (= ribbons).

The tracts are named after the names of masses of grey matter connected by them. Their names usually consist of two components (or terms), the first term denotes the origin and second the termination of the tract. For example, a tract arising in cerebral cortex and terminating in the spinal cord is called **corticospinal tract**. Similarly, a tract arising in the spinal cord and

terminating in the thalamus is called **spinothalamic tract** (Fig. 20.9 ).

**FIG. 20.9 ■** Transverse section of the spinal cord at mid-cervical level showing mainly descending (on left side) and ascending (on right side) tracts.

**Classification of the tracts**

The spinal cord contains two main type of tracts, viz. types: descending and ascending (Fig. 20.9 ).

The distribution of different descending and ascending tracts in three white columns (anterior, lateral, and posterior) of the spinal cord are summarized in Table 20.3 .

**TABLE 20.3**

**Presence of different tracts in anterior, lateral, and posterior white columns of the spinal cord**

Column	Descending tracts	Ascending tracts
Anterior white column	Anterior corticospinal, vestibulospinal, tectospinal, medial reticulospinal	Anterior spinothalamic
Lateral white column	Lateral corticospinal, rubrospinal, lateral reticulospinal,	Lateral spinothalamic, anterior spinocerebellar, posterior spinocerebellar, spinotectal

	hypothalamospinal	
Posterior white column		<ul style="list-style-type: none"> <li>• Fasciculus gracilis (tract of Goll)</li> <li>• Fasciculus cuneatus (tract of Burdach)</li> </ul>

### **Descending tracts AN 57.4**

The descending tracts conduct the impulses from the brain to the spinal cord.

### **Pyramidal tract (Fig. 20.10 )**

The pyramidal tract consists of *corticospinal and corticobulbar/corticonuclear tracts* , but mostly of corticospinal tract; hence, corticospinal tract is mostly termed as pyramidal tract.

**FIG. 20.10 ■** Pyramidal tracts (corticospinal tract is shown in *red* and corticobulbar in *blue* ).

The pyramidal tract consists of approximately 1 million fibres.

*Origin:* The most of the fibres of corticospinal tracts arise from pyramidal cells (of Betz) of the motor area of the cerebral cortex.

Some fibres arise from other parts of the cortex.

**Course:** The fibres pass through corona radiata, internal capsule, crus cerebri of cerebral peduncles, ventral part of the pons, and pyramids of the medulla oblongata. In the lower part of the medulla, majority of fibres (approximately 75%) cross to the opposite side at the pyramidal decussation of the medulla and descend in the lateral white column of the spinal cord as the **lateral corticospinal tract**. The uncrossed fibres descend in the anterior white column of the spinal cord as the **anterior corticospinal tract**. The lateral corticospinal tract also contains some fibres, which arise from the ipsilateral cerebral cortex.

The **lateral corticospinal tract** lies in the lateral white column in front of the posterior horn and medial to the posterior spinocerebellar tract. The **anterior corticospinal tract** lies in the anterior white column close to the anterior median fissure. Lower down the fibres of anterior corticospinal tract also cross to the opposite side in the anterior white commissure of the spinal cord at the level of their termination.

**Termination:** Most of the fibres of both lateral and anterior corticospinal tracts terminate by synapsing with the interneurons, which in turn project to the motor neurons ( $\alpha$  and  $\gamma$ ) of the anterior horn. Only 2% of the fibres synapse directly with the motor neurons.

### N.B.

- Because of decussation of corticospinal fibres in the medulla (*medullary decussation*), the cerebral cortex of one side controls the muscles of the opposite half of the body.
- As the pyramidal tract traverses the brainstem, the *corticobulbar fibres* / *corticonuclear fibres* (shown in blue colour in Fig. 20.10) supply the motor nuclei of the cranial nerves of opposite side. Thus, the pyramidal tract also includes corticobulbar fibres.

### CLINICAL CORRELATION

**Effects of lesions of pyramidal tract:** The lesions of pyramidal tract above the level of decussation, will cause *upper motor neuron (UMN)* type of paralysis on the opposite half of the body below the level of the lesion. with symptoms such as spastic paralysis, hyperreflexia, positive Babinski sign on the opposite side of the body. While lesions below the level of decussation

will also cause UMN type of paralysis, but on the same side. The muscles are not actually paralysed but the control on the motor neuron supplying them, *i.e. lower motor neurons (LMNs)* is lost. As a result, the tone of muscles is increased leading to *spastic paralysis* .

### **Rubrospinal tract**

The fibres of this tract arise from the cells of the red nucleus (nucleus ruber) located in the midbrain and immediately caudal to red nucleus they decussate with those of the opposite side and descend as a compact bundle in the lateral white column of the spinal cord, ventral to the lateral corticospinal tract. The fibres of this tract end just like those of corticospinal tract in the anterior horn cells of the spinal cord. This tract forms a part of extrapyramidal system.

Rubrospinal tract facilitates the activity of the flexor muscles and inhibits the activity of the extensor antigravity muscles.

### **Reticulospinal tract**

#### **Lateral reticulospinal tract**

This tract lies in the lateral white column. Its fibres arise from cells of the reticular formation in the brainstem (midbrain, pons, and medulla) and relay in the anterior horn cells. This tract exerts facilitatory influence on the motor neurons, which supply the skeletal muscles.

#### **Medial reticulospinal tract**

It lies in the anterior white column. Its fibres arise from the cells of the reticular formation in the medulla and relay in the anterior horn cells of the spinal cord. This tract exerts inhibitory influence on the motor neurons supplying the skeletal muscles.

### **N. B.**

The reticulospinal fibres are now thought to be included in descending autonomic fibres. The reticulospinal tracts thus provide a pathway by which the hypothalamus can control the thoracolumbar sympathetic outflow and the sacral parasympathetic outflow.

### **Hypothalamospinal tract**

It projects from the hypothalamus and descends in the lateral white column of the spinal cord on the medial side of the lateral corticospinal tract and

terminates by synapsing with lateral horn cells of T1–L2 spinal segments responsible for sympathetic outflow, and lateral horn cells of S2, S3, and S4 spinal segments responsible for parasympathetic outflow.

### **Ascending tracts AN 57.4**

The ascending tracts conduct the impulses from the periphery to the brain through the cord.

The important ascending tracts fall into the following three types:

1. Those concerned with *pain and temperature sensations and crude touch* , are: *lateral and anterior spinothalamic tracts* .
2. Those concerned with *fine touch and conscious proprioceptive sensations* , are: *fasciculus gracilis and fasciculus cuneatus* .
3. Those concerned with *unconscious proprioception and muscular coordination* , are: *anterior and posterior spinocerebellar tracts* .

### **N.B.**

Ascending tracts associated with perception of conscious proprioception consist of three neural pathways, whereas those concerned with the unconscious proprioception are made up of only two neural pathways.

### **Ascending tract concerned with conscious sensations**

These are:

- Lateral spinothalamic tract
- Anterior spinothalamic tract
- Fasciculus gracilis and fasciculus cuneatus.

### **Lateral spinothalamic tract (Fig. 20.11 )**

It carries sensations of pain and temperature from opposite side of body.

**FIG. 20.11 ■** Lateral and anterior spinothalamic tracts.

The cell bodies of first-order sensory neurons (pseudounipolar neurons) of this tract lie in the dorsal root ganglia of the spinal nerves. The central processes of these cells enter the cord through the lateral division of the dorsal root of the spinal nerves. In the cord, the fibres ascend one or two segments as the **dorsolateral tract of Lissauer** at the tip of posterior horns and then relay in the posterior horn by synapsing with the cells of substantia gelatinosa. The axons of second-order sensory neurons of substantia gelatinosa cross to the opposite side in the anterior white commissure and ascend up as **lateral spinothalamic tract** in the opposite lateral white column just lateral to the anterior horn. They terminate in the **ventral posterolateral nucleus (VPL) of the thalamus**. The **axons of the third-order sensory neurons** project to the primary sensory cortex of the cerebral hemisphere for perception of sensations.

## CLINICAL CORRELATION AN 57.5

The fibres of this tract carry pain and temperature sensations – the pain fibres being lateral to the temperature. The pain fibres relatively become very superficial in the lateral white column of the cord in the cervical region. Therefore, **cordotomy** can be performed safely at this level to relieve pain in the opposite half of the body.

The involvement of decussating fibres of this tract in the anterior commissure in **syringomyelia** leads to bilateral loss of pain and temperature sensations at the level of the lesion. The syringomyelia is the development of fluid-filled cysts (syrinx) around the central canal of spinal cord.

### Anterior spinothalamic tract

It carries sensation of crude touch and pressure tickle from opposite half of the body.

The cell bodies of the **first-order sensory neurons** of this tract lie in the dorsal root ganglia of the spinal nerves. The central processes of these cells (large and heavily myelinated) enter the cord through the medial division of the dorsal roots of the spinal nerves and ascend in the cord one or two segments as the **dorsolateral tract of Lissauer** and relay in the substantia gelatinosa of the posterior horn. The axons of **second-order sensory neurons** of substantia gelatinosa cross the midline in the anterior white commissure and then ascend as **ventral spinothalamic tract** in the opposite anterior white column just in front of the anterior horn. These fibres terminate in the ventral posterolateral nucleus of the thalamus ([Fig. 20.11](#)).

The axons of **third-order neurons** arise from VPL nucleus of thalamus and relay in sensory cortex for perception of sensation.

### N.B.

The lateral spinothalamic tract carries pain and temperature sensations, whereas anterior spinothalamic tract carries sensations of crude touch and pressure.

## CLINICAL CORRELATION

The **damage of anterior spinothalamic tract** leads to loss of crude touch and pressure on the opposite side of the body below the level of the lesion.

**Fasciculus gracilis (tract of goll) and fasciculus cuneatus (tract of**

## burdach)

They carry sensations of conscious proprioception, i.e., conscious body movements and position from opposite half of the body.

These two tracts occupy the posterior white column of the cord, the tract of Goll being medial to the tract of Burdach. They carry sensations of **conscious proprioception**, two-point tactile discrimination, and vibration. The cell bodies of the first-order sensory neurons lie in the dorsal root ganglia of the spinal nerves. The central processes of these cells (thickly myelinated) enter the cord through the medial division of the dorsal root and continue in the posterior white column as fasciculus gracilis and fasciculus cuneatus (Fig. 20.12 ).

**FIG. 20.12 ■** Fasciculus gracilis and fasciculus cuneatus (posterior column-medial lemniscus pathway).

Fibres from the coccygeal, sacral, lumbar, and lower thoracic segments ascend up in the tract of Goll, whereas the fibres from the upper thoracic and cervical segments run in the tract of Burdach. The cervical, thoracic, lumbar, and sacral fibres are arranged in that order from lateral to medial in these tracts.

The fibres of fasciculus gracilis and fasciculus cuneatus terminate in nucleus gracilis and nucleus cuneatus, respectively. The axons of second-order sensory neurons from nucleus gracilis and nucleus cuneatus curve ventromedially around the central grey matter of the medulla as internal arcuate fibres to undergo decussation. The fibres after crossing the midline turn upwards as a flat tract called **medial lemniscus**, which courses upward to terminate in the ventral posterolateral nucleus (VPL) of the thalamus. The third-order sensory neurons from thalamus project into the cerebral cortex of the cerebral hemisphere. This pathway carrying conscious proprioceptive sensations is termed as **dorsal column-medial lemniscus pathway**.

### CLINICAL CORRELATION

**Romberg sign:** The involvement of posterior white columns and posterior nerve roots in syphilitic degenerative disease called *tabes dorsalis* leads to loss of sense of position. The patient is not able to tell the position or movements of his or her lower limbs unless he or she sees them. Therefore, when he or she is asked to stand up with his or her feet together and eyes closed, he or she staggers and falls because he or she cannot maintain his or her correct position because of lack of proprioceptive information (*Romberg sign*).

### Ascending tracts concerned with unconscious propriosensation

These are:

- Spinocerebellar tracts
- Cuneocerebellar tract.

### Spinocerebellar tracts (Fig. 20.13)

They carry unconscious proprioceptive sensations from same side of the

body.

**FIG. 20.13** ■ Schematic diagram showing the posterior (red) and anterior (blue) spinocerebellar tracts.

The spinocerebellar fibres are located in the lateral white column of the cord and are divided into two tracts: **posterior spinocerebellar tract** and **anterior spinocerebellar tract** according to their location in the cord. They carry unconscious proprioceptive sensations from cord to the cerebellum and play an important role in muscular coordination.

### Posterior (dorsal) spinocerebellar tract

The cell bodies of the **first-order sensory neurons** lie in the dorsal root ganglia of the spinal nerves. The central processes of these cells enter the posterior horn of the grey matter through posterior roots of spinal nerves and relay in the *nucleus dorsalis (Clarke's column)*. The axons from cells of nucleus dorsalis (**second-order sensory neurons**) pass to the dorsolateral part of the white column on the same side and ascend as *posterior*

*spinocerebellar tract* . The fibres of the tract enter the cerebellum through the inferior cerebellar peduncle and terminate in the ipsilateral cerebellar cortex.

### Anterior (ventral) spinocerebellar tract

The origin and course of the first-order sensory neurons is same as that of posterior spinocerebellar tract. The axons of cells of nucleus dorsalis (second-order sensory neurons) cross to the opposite side and pass to the anterolateral part of the lateral white column of the spinal cord and then ascend to form the anterior spinocerebellar tract. The fibres of anterior spinocerebellar tract reach up to midbrain and then enter the cerebellum through its **superior cerebellar peduncle** to terminate in the ipsilateral cerebellar cortex.

The input of both posterior and anterior spinocerebellar tracts is ipsilateral.

Functionally, both posterior and anterior spinocerebellar tracts carry impulses from the lower limb. The posterior tract is concerned with fine movements, whereas anterior tract is concerned with gross movements of the limb as a whole.

### Cuneocerebellar tract

It is similar to the posterior spinocerebellar tract. However it specifically, conveys information from upper limbs.

### N.B.

Since Clarke's nucleus is not present above the level of C8 spinal segment, the afferent fibres from upper limb pass to the medulla via *cuneate fasciculus* and synapse in accessory *cuneate nucleus* .

### CLINICAL CORRELATION

- **Subacute combined degeneration of the spinal cord:** It occurs because of deficiency of vitamin B<sub>12</sub> . In this condition, the posterior white columns and lateral corticospinal tracts undergo degeneration on both sides. It usually affects the lumbosacral segments. Clinically, it presents with the following signs and symptoms:
  - ☞ Bilateral loss of position and vibratory sense
  - ☞ Spastic paraplegia with exaggerated tendon reflexes and positive Babinski sign.
- **Spinal cord injury:** In *complete transection of spinal cord* , there is

loss of movements and all sensations below the level of the injured segment.

*In hemisection of spinal cord (Brown-Séquard syndrome) , there is ipsilateral spastic paralysis due to lesion of corticospinal tract, contralateral loss of pain and temperature sensations and ipsilateral loss of conscious proprioception and sense of vibration due to lesions of lateral spinothalamic tract and dorsal column-medial lemniscus pathway, respectively.*

To summarize, the motor impulses travel from the brain to the anterior horn cells of spinal cord through the descending tracts and then out to the periphery via the spinal nerves. The sensory impulses from the periphery travel through spinal nerves into the spinal cord via posterior or dorsal horn and then up the spinal cord to the brain through ascending tracts.

## **Blood supply of spinal cord**

### **Arterial supply**

The spinal cord is supplied by the following arteries:

1. Anterior spinal artery
2. Posterior spinal arteries
3. Segmental arteries.

### **Anterior spinal artery**

The anterior spinal artery is formed by the union of two small spinal branches of the right and left vertebral arteries in the upper cervical canal. It runs caudally in the anterior median fissure of the spinal cord and terminates along the filum terminale.

### **Posterior spinal arteries**

There are two posterior spinal arteries each arising as a small branch from either the vertebral or posterior inferior cerebellar artery. Each posterior spinal artery runs down on the posterolateral aspect of the cord in the posterolateral sulcus along the line of attachment of posterior nerve roots and usually divides into two collateral arteries along the medial and lateral side of the posterior nerve roots. Thus, there are five longitudinal arteries around the spinal cord.

These arteries are reinforced by the segmental arteries (feeder arteries) to form five longitudinal arterial trunks. These arterial trunks communicate around the cord forming a pial plexus, the **vasocorona/arteriae coronae** . The arteriae coronae give peripheral branches, which supply the superficial regions of the cord.

*Anterior spinal artery supplies the anterior two-third of the cord, whereas two posterior spinal arteries together supply the posterior one-third of the cord.*

## CLINICAL CORRELATION

**Anterior spinal artery syndrome:** It occurs because of occlusion (thrombosis or compression of the anterior spinal artery).

As the anterior spinal artery supplies anterior two-third of the cord, occlusion of this artery will result in the following signs and symptoms:

- (a) *Motor symptoms* due to involvement of corticospinal tracts and anterior grey columns.
- (b) Sensory symptoms (namely bilateral loss of pain and temperature sensation) due to ischaemia of spinothalamic tracts.

The conscious proprioceptive sensations are preserved because the region of posterior white column is supplied by posterior spinal arteries.

## Segmental arteries

The segmental arteries are spinal branches of *deep cervical, ascending cervical, posterior intercostal, lumbar, and lateral sacral arteries* . They reach the spinal cord as the anterior and posterior radicular arteries along the corresponding roots of the spinal nerves, respectively. They mainly nourish the nerve roots.

The largest segmental (radicular) arteries at the 1st (T1) and 11th thoracic (T11) segmental levels are often termed as **arteria radicularis magna (arteries of Adamkiewicz)** .

## Venous drainage

The veins draining the cord form six longitudinal venous channels around the cord, namely:

1. **Two median longitudinal** , one in the anterior median fissure and

the other in the posteromedian sulcus.

2. **Two anterolateral** , one on either side, posterior to the anterior nerve roots.
3. **Two posterolateral** , one on either side, posterior to the posterior nerve roots.

These longitudinal venous channels communicate with the **internal vertebral venous plexus** and drained by veins, which leave through the intervertebral foramina to empty into the vertebral, posterior intercostal, lumbar, and lateral sacral veins.

The internal vertebral venous plexus communicates above with the basilar venous plexus.

### **Golden Facts to Remember**

• <b>Most important descending tract of the spinal cord</b>	Corticospinal tract (pyramidal tract)
• <b>Most important ascending tracts of the spinal cord</b>	Lateral and anterior spinothalamic tracts
• <b>Cauda equina</b>	Leash of spinal nerve roots around filum terminale arising from conus medullaris, resembling the tail of a horse
• <b>Largest artery supplying the spinal cord</b>	Anterior spinal artery
• <b>Artery supplying most of the substance of spinal cord</b>	Anterior spinal artery supplying anterior two-third of the cross-sectional area of the spinal cord
• <b>Positional changes of lower end of spinal cord in the developing spinal cord</b>	<ul style="list-style-type: none"><li>– <i>In foetus</i>: S2 vertebra (lower border)</li><li>– <i>At birth</i>: L3 vertebra (lower border)</li><li>– <i>In adult</i>: L1 vertebra (lower border)</li></ul>
• <b>All sensory ganglia (spinal ganglia) of spinal nerves lie in</b>	First two cervical, sacral and coccygeal spinal nerves

<b>the intervertebral foramina except those of</b>	
<b>• Most susceptible spinal segments to ischaemic necrosis</b>	T4 and L1 spinal segments
<b>• Level of termination of spinal cord</b>	In adults L1 and in children L3 vertebrae, respectively

## CLINICAL CASE STUDY

A 47-year-old patient went to a neurologist and complained to him of motor and sensory symptoms, which he had noticed in the last few months. After thorough neurological examination, he was diagnosed as a case of **subacute combined degeneration of the spinal cord**.

### Questions

1. What is the cause of subacute combined degeneration of the spinal cord?
2. Name the main tracts which undergo degeneration in this condition.
3. Mention the characteristic signs and symptoms of this condition.
4. Which spinal segments are usually affected in this condition?

### Answers

1. Degeneration of dorsal columns and lateral columns of spinal cord due to demyelination. It usually occurs due to deficiency of vitamin B<sub>12</sub>.
2. Fasciculus gracilis, fasciculus cuneatus, spinocerebellar tracts, and lateral corticospinal tracts.
3. The characteristic signs and symptoms of the condition are as follows:
  - (a) Bilateral loss of position and vibratory sense, ataxia and gait disturbance.
  - (b) Spastic paralysis with exaggerated tendon reflexes and positive Babinski sign.
4. Lumbosacral segments.

---

# Chapter 21: Cranial cavity, cranial meninges and pituitary gland

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the cranial cavity, its subdivisions, foramina, and structures passing through them. **AN 26.3**
- Describe the cranial fossae and identify related structures. **AN 30.1**
- Describe and identify major foramina with structures passing through them. **AN 30.2**
- Describe and identify dural folds and dural venous sinuses. **AN 30.3**
- Describe the clinical importance of dural venous sinuses. **AN 30.4**
- Explain the effects of pituitary tumours on visual pathway. **AN 30.5**
- Describe the cavernous sinus under the following headings: (a) formation and location, (b) relations, (c) contents, (d) tributaries and communications, and (d) applied anatomy.
- Enumerate the various dural folds. Describe falx cerebri and tentorium cerebelli in detail.
- Draw a labelled diagram to show cavernous sinuses as seen in coronal section.

## Cranial cavity

The cranial cavity is the main cavity of the skull. It lodges the brain, meninges, portions of the cranial nerves, and blood vessels. It is roofed over by the skull cap, and its floor is formed by the upper surface of the base of the

skull (Fig. 21.1 ).

**FIG. 21.1 ■** Parasagittal section of skull showing anterior, middle, and posterior cranial fossae. The inset shows the levels of anterior, middle, and posterior cranial fossae akin to three terraces with descending levels.

## Skull cap (calvaria)

The skull cap or the vault of the skull forms roof of the cranial cavity. It is made up of outer aspects of frontal, parietal, and occipital bones.

## Surfaces

**External surface:** The external surface of the skull cap or calvaria has been described in [Chapter 2](#) .

**Internal surface (Fig. 21.2 ):** The internal surface appears as an ovoid

hollow plate of bone and presents the following features ([Fig. 21.2](#)):

1. *Coronal, sagittal, and lambdoid sutures.*
2. *Sagittal sulcus:* It is an anteroposterior groove in the median plane, which lodges the superior sagittal sinus. When traced posteriorly, it becomes wider, and at internal occipital protuberance, it becomes continuous with the right transverse sulcus.
3. *Granular pits:* These are numerous irregular depressions on each side of the sagittal sulcus, which lodge **arachnoid granulations**. They are more prominent in skulls of elderly people.
4. *Vascular grooves:* These are produced by the terminal branches of middle meningeal vessels. Groove for the anterior branch is located behind the coronal suture, whereas that for the posterior (parietal) branch is more posteriorly placed.
  - The terminal branches of middle meningeal artery are separated from bone by their corresponding veins; hence, the vascular grooves are mostly produced by the veins rather than by the arteries.
5. *Parietal foramina:* It is one on each side close to the sagittal sulcus approximately 3.5 cm in front of the lambda.
6. *Impression for cerebral gyri:* They are rather less marked as compared to those on the internal surface of the base of the skull.

**FIG. 21.2 ■** Internal surface of the vault of the skull (calvaria).

### Structure of skull cap

The bones of skull cap (cranial vault) consist of outer and inner layers/plates of compact bone (generally called *outer and inner tables* ) with an intervening layer of the spongy bone called **diploë** .

### **N.B.**

In children, the bones of cranial vault are made of a single layer of the compact bone.

The outer table is thick, resilient, and tough, whereas the inner table is thin and brittle. The blows on head may cause fractures of either one or both the tables. When the inner table is fractured, it has tendency to shatter and can

lacerate the underlying vessels within the dura mater. The diploë is filled with red bone marrow.

### Diploic veins

The blood from the diploë is drained by diploic veins ([Fig. 21.3](#)). These veins drain mostly into the intracranial dural venous sinuses. They lack valves and communicate with the veins draining the scalp that clothe the cranial vault. The recognizable diploic veins are usually four on each side and descend almost vertically to open into the nearest convenient venous sinus. These are as follows:

1. A **frontal diploic vein** that emerges from the bone in the supraorbital foramen to join the supraorbital vein.
2. An **anterior temporal (parietal) diploic vein** that pierces the greater wing of the sphenoid to join the sphenoparietal sinus or the anterior deep temporal vein.
3. A **posterior temporal (parietal) diploic vein** that pierces the inner table in the parietomastoid angle to join the transverse sinus.
4. An **occipital diploic vein** (the largest) that pierces the inner table near the internal occipital protuberance to join the transverse sinus near the confluence of sinuses or into an occipital emissary vein.

**FIG. 21.3 ■** Diploic veins displayed by the removal of the outer table of the vault of the skull.

### Clinical significance

- (a) Provide alternate route of venous drainage if dural venous sinuses are blocked
- (b) Provide routes for infections.

### Subdivisions of the cranial cavity AN 30.1

The floor of cranial cavity is divided into three distinct portions. From before backwards, these are **anterior cranial fossa**, **middle cranial fossa**, and **posterior cranial fossa**, respectively.

*The floor of the cranial cavity is akin to three descending 'steps' by two sharp bony ridges on each side , namely the posterior free border of the lesser wing of the sphenoid (**sphenoidal ridge** ) in front, and the sharp superior border of the petrous temporal bone (**petrous ridge** ) behind (Fig. 21.4 ).*

**FIG. 21.4 ■** Floor of the cranial cavity (the internal surface of the base of the skull). DS, dorsum sellae. ACF= anterior cranial fossa; MCF= middle cranial fossa; PCF= posterior cranial fossa. Figure in the inset on the right shows three descending steps akin to levels of floor of three cranial fossae.

The three steps are known as the **anterior, middle, and posterior cranial fossae**. Thus, the anterior cranial fossa is at the highest level, the posterior cranial fossa at the lowest level, and the middle cranial fossa at the middle level.

The internal surface of the base of the skull is divided into the anterior, middle, and posterior cranial fossae. They are arranged like three terraces with descending levels (Fig. 21.1, inset).

### **Anterior cranial fossa AN 57.4**

The anterior cranial fossa lodges the frontal lobes of the cerebral hemispheres. Its floor is composed of the portions of the following three bones: ethmoid, frontal, and sphenoid (Fig. 21.4). It is demarcated from the

middle cranial fossa by:

- (a) Posterior free border of the lesser wing of sphenoid on each side
- (b) Anterior border of the sulcus chiasmaticus in the median region.

The junction between these two is marked by the anterior clinoid process.

## Features

The anterior cranial fossa presents the following features:

1. In the **median region**, from before backward these are as follows:
  - (a) *Frontal crest*, a vertical crest on the inner aspect of the frontal bone.
  - (b) *Foramen caecum* (in between the frontal crest and crista galli).
  - (c) *Crista galli*, a cock's comb-like bony crest, formed by the perpendicular plate of the ethmoid.
  - (d) *Jugum sphenoidale* (the superior surface of the anterior part of the body of the sphenoid).
  - (e) On each side of crista galli lies the sieve-like *cribriform plate of the ethmoid*, which separates the anterior cranial fossa from the nasal cavity. It possesses:
    - *A number of small foramina*, to provide passage for 15–20 filaments of the olfactory nerve
    - *Nasal slits* one on either side of crista galli to provide passage to the anterior ethmoidal nerve and vessels
    - *An anterior ethmoidal canal* along the lateral border anteriorly and a *posterior ethmoidal canal* along the lateral border posteriorly to provide passage to the anterior and posterior ethmoidal nerve and vessels.
2. In the **lateral region** on either side, orbital plate of the frontal bone separates anterior cranial fossa from the orbit and supports the frontal lobe of the brain with consequent impressions of sulci and gyri.

## Structures passing through various foramina in anterior cranial fossa AN 30.2

### Foramen caecum

**Emissary vein** from the nasal mucosa to the anterior end of the superior sagittal sinus if foramen is patent.

## Cribriform foramina

**Olfactory nerves surrounded by leptomeninges (pia and arachnoid maters):** from the olfactory epithelium of the nasal cavity to the olfactory bulb in the anterior cranial fossa.

## Anterior ethmoidal foramen

1. Anterior ethmoidal nerve: a branch of the nasociliary nerve
2. Anterior ethmoidal artery: a branch of the ophthalmic artery
3. Anterior ethmoidal vein: a tributary of the ophthalmic vein

## Posterior ethmoidal foramen

1. Posterior ethmoidal nerve: a branch of the nasociliary nerve
2. Posterior ethmoidal artery: a branch of the ophthalmic artery
3. Posterior ethmoidal vein: a tributary of the ophthalmic vein

## CLINICAL CORRELATION

**Foramen caecum** may transmit an emissary vein from the nasal cavity to the superior sagittal sinus and then serves as a potential route for spread of nasal infections to the meninges of the cranial cavity.

## Middle cranial fossa

### Floor of middle cranial fossa (Fig. 21.4 )

The floor of middle cranial fossa resembles a butterfly – consisting of a small median part and an expanded lateral part on each side.

The middle cranial fossa is demarcated from anterior cranial fossa by:

- (a) The *posterior free border of the lesser wing* of the sphenoid on each side.
- (b) The *limbus sphenoidalis* in the median region. The limbus is an anterior edge of shallow transverse area called **sulcus chiasmaticus**.

The middle cranial fossa is demarcated from the posterior cranial fossa by:

- (a) The superior border of the petrous temporal bone on each side
- (b) The dorsum sellae (a rectangular plate of bone) in the median region.

## Median part of middle cranial fossa

The median part of the middle cranial fossa is formed by the body of the sphenoid, which is more or less cuboidal.

The median region, from before backward, presents the following features:

1. **Sulcus chiasmaticus**, leading on each side into the optic canal which opens into the orbit.
2. **Sella turcica (Turkish saddle)**. It is the hollowed out upper surface of the body of the sphenoid (*hypophyseal fossa*) bounded in front by the tuberculum sellae – the posterior edge of sulcus chiasmaticus – and behind by the dorsum sellae. The lateral ends of the tuberculum sellae bear the middle clinoid processes and the lateral ends of the dorsum sellae bear the posterior clinoid processes.

The sella turcica consists of three parts: the tuberculum sellae, the hypophyseal fossa, and the dorsum sellae. The hypophyseal fossa is occupied by the pituitary gland in life.

The **carotid groove** is a shallow sulcus on either side of the body of the sphenoid lateral to the hypophyseal fossa. It begins at the foramen lacerum, runs upward, then forward and finally upward again to end medial to the anterior clinoid process. The internal carotid artery occupies this groove.

Sometimes, the middle and anterior clinoid processes are united by a bony bar forming **caroticoclinoid foramen** for the passage of internal carotid artery.

### N. B.

The median part (region) of the middle cranial fossa is likened to a bed with four clinoid processes, superior border of petrous temporal bone representing the four bed posts (Greek, *Kline* = a bed).

## Lateral part of middle cranial fossa

The lateral part of the middle cranial fossa on each side is formed by upper surface of the greater wing of the sphenoid together with the anterior surface of the petrous temporal bone and squamous part of the temporal bone. It lodges the temporal lobe of the cerebral hemisphere.

It is limited in front by sharp posterior border of the lesser wing of the sphenoid, and behind by sharp upper border of the petrous temporal bone. These bony ridges are related to the sphenoparietal and superior petrosal

sinuses, respectively.

## Greater wing of the sphenoid

The greater wing of the sphenoid presents:

1. **Four foramina** arranged roughly in a semicircular array (Fig. 21.5 ).  
From behind forward, these are as follows:
  - (a) *Foramen spinosum* is posterior-most and located at the posterior tip of the greater wing. It is so called because on the undersurface of the greater wing at this point is the **spine of sphenoid** .
  - (b) *Foramen ovale* is located just in front and medial to the foramen spinosum. The reason for its name is obvious.
  - (c) *Foramen rotundum* is in front and medial to the foramen ovale. It leads downward and forward into the pterygopalatine fossa.
  - (d) *Superior orbital fissure* (an elongated triangular fissure) is in front and lateral to foramen rotundum under the overhanging shelf of the lesser wing of the sphenoid. *It is actually located between the lesser and greater wings of the sphenoid.*
    - Of these four openings, however, only the first two can be seen on the inferior surface of the base of the skull.

### N.B.

In addition to the four foramina, sometimes two more foramina are present in the greater wing of the sphenoid. These are as follows:

- *Emissary sphenoidal foramen (of Vesalius)*: It lies medial to foramen ovale and conveys an emissary vein from the cavernous sinus.
- *Canaliculus innominatus*: It is located on a bar of bone between the foramen ovale and foramen spinosum. It transmits the lesser petrosal nerve when the latter does not pass through foramen ovale.

2. **Groove for middle meningeal vessels** *leads forward from the foramen spinosum*: After a short distance, the groove divides into the anterior and posterior grooves, which lodge the anterior and posterior branches of middle meningeal vessels. The anterior groove continues to the pterion and then arches upward and backward across the parietal bone. At the pterion, the groove may be converted into a *bony tunnel* , thereby increasing the possibility of tearing the middle

meningeal vessels in trauma on the side of the skull in the pterion region.

◦The posterior groove passes backward across the squamous part of the temporal bone.

3. **Foramen lacerum** lies at the posterior end of the carotid groove on the side of the body of the sphenoid, posteromedial to the foramen ovale. It is actually a gap between the petrous temporal and sphenoid bones.
4. **Anterior surface of the petrous temporal bone** presents the following five features:
  - (a) **Trigeminal impression** , a shallow depression medially near the apex of the bone. The trigeminal ganglion lies on this depression.
  - (b) **Hiatus and groove for the greater petrosal nerve:** In front of arcuate eminence, a slit or hiatus for the greater petrosal nerve is continued as a groove to the foramen lacerum.
  - (c) **Hiatus and groove for the lesser petrosal nerve** lie lateral to hiatus and groove for the greater petrosal nerve and lead to the foramen ovale or canaliculus innominatus, if present.
  - (d) **Arcuate eminence** (a rounded elevation) produced by the underlying superior semicircular canal is located at the middle of the anterior surface of the petrous temporal bone.
  - (e) **Tegmen tympani** , a thin plate of bone anterolateral to the arcuate eminence. It forms the roof of middle ear (tympanic cavity). Its anterior part turns downward into the squamotympanic fissure.

**FIG. 21.5** ■ The four foramina in the greater wing of the sphenoid are present along a crescentic line, in its medial part.

**The inner surface of the squamous part of the temporal bone** is grooved by the middle meningeal artery and its terminal anterior and posterior branches.

### **Structures passing through various canals and foramina in the middle cranial fossa AN 30.2**

#### **Optic foramen**

1. **Optic nerve:** Along with its sheath of meninges, that is dura mater, arachnoid mater, and pia mater.
2. **Ophthalmic artery:** A branch of cerebral part of the internal carotid artery.
3. Sympathetic plexus around the ophthalmic artery.

#### **Superior orbital fissure (Fig. 21.6 )**

This fissure is divided into three parts, central, lateral and medial by means of the *common tendinous ring of Zinn*.

- *Structures passing through central part, i.e. the part present within the common tendinous ring:*
  - (a) Superior and inferior divisions of the oculomotor (3rd cranial) nerve.
  - (b) Nasociliary nerve: It lies between the two divisions of the oculomotor nerve.
  - (c) Abducent (6th cranial) nerve: It lies lateral to the nasociliary nerve.
  - (d) Sympathetic root of the ciliary ganglion: It lies between the nasociliary nerve and the lower division of the oculomotor nerve.
- *Structures passing through the lateral part, i.e. part present above and lateral to the common tendinous ring:*
  - (a) Trochlear (4th cranial) nerve
  - (b) Frontal nerve
  - (c) Lacrimal nerve
  - (d) Lacrimal artery
  - (e) Superior ophthalmic vein
  - (f) Recurrent meningeal branch of lacrimal artery
- *Structures passing through the medial part, i.e. part present below and medial to the common tendinous ring:*
  - Inferior Ophthalmic Vein.

**FIG. 21.6 ■** Structures passing through the superior orbital fissure.

## Foramen rotundum

- (i) Maxillary nerve
- (ii) Emissary vein

## Foramen ovale (mnemonic: MALE)

- (i) **M**andibular nerve
- (ii) **A**ccessory meningeal artery
- (iii) **L**esser petrosal nerve
- (iv) **E**missary vein: connecting the pterygoid venous plexus to the cavernous sinus

## Foramen spinosum

- (i) Middle meningeal artery
- (ii) Nervus spinosus

## Foramen lacerum (**Fig. 21.7** )

- (i) Meningeal branch of the ascending pharyngeal artery
- (ii) Emissary vein: from the cavernous sinus to the pharyngeal venous plexus
- (iii) Internal carotid artery along with the sympathetic plexus around it, enters it from behind and exits above
- (iv) Greater petrosal nerve enters from posterolateral aspect and leaves anteriorly as a nerve of pterygoid canal

### **N.B.**

Internal carotid artery and greater petrosal nerve do not pass through and through foramen lacerum.

**FIG. 21.7** ■ Structures passing through the foramen lacerum.

The greater petrosal nerve joins the deep petrosal nerve derived from the sympathetic plexus around the internal carotid artery to form the nerve of the pterygoid canal (Vidian nerve), which passes through the pterygoid canal. The posterior orifice of the pterygoid canal lies in the lower part of the anterior wall of the foramen lacerum.

### **CLINICAL CORRELATION**

**Fracture of middle cranial fossa:** The middle cranial fossa is the most common site of fracture of the base of the skull. It is partly because of its position and partly because it is weakened by numerous foramina and canals. In fracture of the middle cranial fossa, the tegmen tympani is usually fractured and the tympanic membrane is torn. As a result, there is *bleeding from the external acoustic meatus* and a leakage of cerebrospinal fluid (called *cerebrospinal otorrhoea*).

The facial and vestibular cochlear nerves may be damaged. Bleeding may occur through nose and mouth if the body of the sphenoid is fractured. Vertigo may occur if semicircular canals are involved.

**Posterior cranial fossa (Fig. 21.4)**

The posterior cranial fossa is the deepest of all cranial fossae and lies behind the superior border of the petrous temporal bone and the dorsum sellae of the sphenoid.

It is formed by portions of the sphenoid, temporal, parietal, and occipital bones. It lodges the hindbrain consisting of cerebellum, pons, and medulla oblongata. The posterior cranial fossa is limited above by the tentorium cerebelli (a wide tent-shaped fold of the dura mater), which intervenes between the occipital lobes of the cerebral hemispheres above and the cerebellum below.

## Features

### 1. **The median area** presents the following features:

- (a) *Clivus* , a sloping surface in front of foramen magnum, is formed by the fusion of the posterior part of the body of sphenoid with the basilar part of the occipital bone. It is separated from the petrous temporal bone by petro-occipital fissure, which ends posteriorly at *jugular foramen* .
- (b) *Foramen magnum* , the largest foramen of the skull, is present in the lowest part of the posterior cranial fossa.
  - On each side of the foramen magnum, a little above the lateral margin of its anterior part lies the *hypoglossal canal*.

### 2. **The squamous part of the occipital bone** shows the following features:

- (a) *Internal occipital crest*: It is a vertical bony ridge, running downward from the internal occipital protuberance to the foramen magnum.
- (b) *Internal occipital protuberance* : It is located opposite to the external occipital protuberance.
- (c) *Grooves for the transverse and sigmoid sinuses*: The grooves for the transverse sinus, one on either side, run laterally from the internal occipital protuberance to the mastoid angle of the parietal bone where it becomes continuous with the groove for the sigmoid sinus, which ends into the posterior part of the jugular foramen.
- (d) *Cerebellar fossa* on each side lies between the transverse and sigmoid grooves and the foramen magnum.
- (e) *Fossae for occipital lobes* one on each side lie above the groove for the transverse sinus.

3. The **posterior surface of the petrous bone** presents the following features:
- (a) *Internal acoustic (auditory) meatus*: It is a bony canal in the centre of the posterior surface, lying almost directly medial to the external acoustic meatus. The meatus is approximately 1 cm in length.
  - (b) *Subarcuate fossa* , an indistinct depression lateral and superior to the internal acoustic meatus. It contains dural fold and some blood vessels.
  - (c) *Aqueduct of vestibule* , a slit behind the internal acoustic meatus. It transmits the endolymphatic duct of the internal ear.
  - (d) *Cochlear canaliculus* , a notch in the lower border of the posterior surface of the petrous bone, just above the anterior end of the jugular foramen. It lodges the cochlear aqueduct.

### **N.B.**

The posterior surface of the petrous temporal bone is triangular and has three borders: superior, inferior, and posterior. Each border is related to a dural venous sinus: the superior border to the *superior petrosal sinus* , the inferior border to the *inferior petrosal sinus* , and the posterior border to the *posterior sigmoid sinus* .

## **Structures passing through various foramina and canals in posterior cranial fossa AN 30.2**

### **Internal auditory meatus**

1. Seventh cranial (facial) nerve (motor root)
2. Eighth cranial (vestibulocochlear) nerve
3. Nervus intermedius (sensory root VII N.)
4. Internal auditory (labyrinthine) vessels

### **Jugular foramen (Fig. 21.8 )**

It may be divided into three parts: anterior, middle, and posterior.

1. **Anterior part:** Inferior petrosal sinus
2. **Middle part:** In anteroposterior direction
  - (a) Ninth cranial (glossopharyngeal) nerve
  - (b) Tenth cranial (vagus) nerve

(c) Eleventh cranial (accessory) nerve

The 10th and 11th cranial nerves are surrounded in a common sheath of the dura mater, whereas the 9th cranial nerve has an independent sheath of the dura mater.

3. **Posterior part:** Sigmoid sinus.

**FIG. 21.8** ■ Structures passing through the jugular foramen.

### Hypoglossal (anterior condylar) canal

1. Twelfth cranial (hypoglossal) nerve
2. Meningeal branch of the ascending pharyngeal artery

### Posterior condylar canal (only sometimes present in the lower part of the sigmoid groove)

1. Emissary vein: connecting the suboccipital venous plexus to the sigmoid sinus
2. Meningeal branch of the occipital artery.

### Foramen magnum (Fig. 21.9 )

It is divided into small anterior and large posterior compartments by means of alar ligaments of axis vertebra:

### 1. **Anterior compartment:**

- (a) Apical ligament of dens
- (b) Upper longitudinal band of the cruciform ligament of atlas
- (c) Membrana tectoria: a continuation of the posterior longitudinal ligament of the vertebral bodies

### 2. **Posterior compartment:**

- (a) Medulla oblongata: along with its meninges, i.e., dura mater, arachnoid mater, and pia mater
- (b) Two posterior spinal arteries (right and left)
- (c) Anterior spinal artery
- (d) Communicating veins between the internal vertebral venous plexus and the basilar venous plexus
- (e) Two vertebral arteries (right and left)
- (f) Sympathetic plexus around the vertebral arteries: this plexus consists of postganglionic sympathetic fibres derived from the inferior cervical sympathetic ganglion
- (g) Spinal roots of two accessory nerves (right and left).

**FIG. 21.9** ■ Structures passing through the foramen magnum.

### **N.B.**

Tonsils of cerebellum project on each side of the medulla oblongata into the large posterior part of the foramen magnum.

## CLINICAL CORRELATION

**Haemorrhage in the posterior cranial fossa:** It mostly occurs due to hypertension or trauma of posterior cranial fossa. It does not become evident at once, unless the basilar part of the occipital bone is fractured and the mucous membrane of the pharyngeal roof is torn.

## Cranial cavity and meninges AN 30.3, AN 56.1

These are three membranes, viz. dura mater, arachnoid mater and pia mater which envelop the brain. The interior of the cranial cavity is lined by the dura mater and the surface of brain is covered by the pia mater. The arachnoid mater lies between these two.

The arachnoid mater is connected to the pia mater by many fine filamentous processes. These two membranes are held together and closely associated with the brain, and therefore, discussed with the brain.

Only dura mater is discussed in detail in this chapter.

### Cranial dura mater

The cerebral dura mater (also called **cranial dura** ) is a strong fibrous membrane consisting of two layers: outer endosteal and inner meningeal layers. The two layers are fused with each other except where they enclose venous sinuses ([Fig. 21.10](#) ).

## **FIG. 21.10 ■ Cranial and spinal dura.**

### **Outer layer (or endosteal layer)**

The outer layer is really the periosteum lining the inner surfaces of the skull bones and is commonly referred to as **endocranium** . It presents the following features:

1. It is continuous with the periosteum (pericranium) on the outer surface of the skull through sutures and the foramina of the skull. It is also continuous with the periosteal lining (periorbita) of the orbit through superior orbital fissure.
2. It provides sheaths for cranial nerves, which fuse with epineurium. The dural sheath around the optic nerve fuses with the sclera of the eyeball.
3. It is loosely attached to the inner surface of the vault of the skull by numerous fibrous and vascular processes; however, it is firmly attached to the base of the skull along the sutures and around the margin of the foramen magnum. As a result, it is easily stripped from the vault of the skull but not from the base of the skull.
4. Meningeal vessels pass through this layer to supply the bone.

### **Inner layer (or meningeal layer)**

The inner layer is really the dura mater proper. It encloses the brain and at the foramen magnum becomes continuous with the dura mater surrounding the spinal cord (i.e., spinal dura). It is separated from the arachnoid mater by a *subdural space*.

At places, meningeal layer is folded on itself to form **dural folds** (also called dural septa). The dural folds project into the cranial cavity and divide it into compartments, which lodge the different parts of the brain ([Fig. 21.11](#) ).

**FIG. 21.11 ■** Coronal section through the posterior cranial fossa showing dural folds and dural venous sinuses enclosed in them. (A) Section through the anterior part. (B) Section through the middle part. (C) Section through the posterior part.

### **Folds of the dura mater**

The folds of the dura mater are:

1. Falx cerebri
2. Tentorium cerebelli
3. Falx cerebelli
4. Diaphragma sellae.

### **Falx cerebri (Fig. 21.12 )**

1. It is a large sickle-shaped fold of the dura mater occupying the median longitudinal fissure between two cerebral hemispheres.
2. Its narrow anterior end is attached to the crista galli and the broad posterior end on to the upper surface of the tentorium cerebelli along the median plane.
3. Its convex upper margin is attached to the lips of the sagittal sulcus of the skull vault and its lower concave margin is free and lies just above the corpus callosum.

**FIG. 21.12 ■** Dural folds and dural venous sinuses enclosed within them, viewed from superolateral aspect.

### **Venous sinuses enclosed in the falx cerebri (Fig. 21.12 )**

1. Superior sagittal sinus is enclosed within the convex upper border.
2. Inferior sagittal sinus is enclosed within the lower concave margin.
3. Straight sinus lies along the line of attachment of the falx cerebri with the tentorium cerebelli.

### **Tentorium cerebelli (Fig. 21.13 )**

It is a tent-shaped fold of the dura mater forming the roof of the posterior cranial fossa. It separates the cerebellum from the occipital lobes of the cerebrum. It has two margins and two surfaces.

**FIG. 21.13** ■ Tentorium cerebelli as seen from above.

## Margins

1. The *inner free margin* is U-shaped and encloses the tentorial notch (incisure) for the passage of the midbrain. The anterior ends of the concave free margin are attached to the anterior clinoid processes.
2. The *outer attached margin* is convex and attached on each side (from before backward) to the posterior clinoid process, superior border of petrous temporal bone, the posteroinferior angle of the parietal bone and the lips of transverse sulci on the occipital bone.

The free and attached margins cross each other near the apex of the petrous temporal bone to enclose a triangular area anteriorly, which is pierced by the oculomotor nerve.

## Surfaces

1. The convex upper surface slopes to either side from the median plane. In the median plane, it provides attachment to falx cerebri.
2. The concave inferior surface provides attachment to falx cerebelli in its posterior part.

### N. B.

**Trigeminal or Meckel's cave** (Fig. 21.14 ): It is a recess of the dura mater present in relation to the attached outer margin of the tentorium cerebelli.

It is formed by the evagination of the meningeal layer of the dura mater by two roots of the trigeminal nerve below the superior petrosal sinus over the trigeminal impression on anterior surface of the petrous temporal bone near its apex.

**FIG. 21.14 ■** Formation of trigeminal cave. (A) Before invagination of the meningeal layer of the dura mater. (B) After invagination of the meningeal layer of the dura mater to form Meckel's cave (cavum trigeminale).

## Venous sinuses enclosed in tentorium cerebelli

1. *Transverse sinus* , within the posterior part of the attached margin
2. *Superior petrosal sinus* , within the anterolateral part of the attached margin

3. *Straight sinus* , along the line of attachment between the falx cerebri and the tentorium cerebelli.

### **Falx cerebelli**

It is a small sickle-shaped fold of the dura mater in the sagittal plane projecting forward into the posterior cerebellar notch. It extends from internal occipital protuberance along internal occipital crest to posterior margin of the foramen magnum. It has a free concave anterior margin and a convex-attached posterior border.

### **Venous sinus enclosed in the falx cerebri**

*Occipital sinus* , along with its posterior attached part.

### **Diaphragma sellae**

It is a small circular horizontal fold of inner layer of the dura mater forming the roof of the hypophyseal fossa.

It is attached *anteriorly* to the tuberculum sellae and *posteriorly* to the dorsum sellae and becomes *continuous* on each side with the dura mater of the middle cranial fossa.

It has a central aperture, which provides passage to the **stalk of the pituitary gland** .

### **Blood supply of dura mater**

*Inner layer:* The inner layer of the dura mater is more fibrous and requires very little blood to nourish it.

*Outer layer:* The outer layer of the dura mater is richly vascular and provides nourishment to the adjacent bone.

*In supratentorial compartment, it is supplied by the following arteries:*

1. **In anterior cranial fossa** – by the meningeal branches of the ophthalmic, anterior, and posterior ethmoidal arteries and a branch of the middle meningeal artery.
2. **In middle cranial fossa** – by the middle and accessory meningeal arteries and the meningeal branches of the internal carotid and ascending pharyngeal arteries.
3. **In posterior cranial fossa** – by the meningeal branches of the vertebral and occipital arteries.

## CLINICAL CORRELATION

**Blood supply of bones of skull:** The *meningeal arteries are the chief source of blood supply to the bones of the skull*. The bones receive very little blood from the vessels of the scalp. As a result, scalping does not produce necrosis of the underlying bone. The skull bones receive blood supply from exterior only where they provide attachment to muscles, namely the temporal fossa and the suboccipital region.

### Nerve supply of the dura mater

**Supratentorial dura** is supplied by the ophthalmic nerve.

**Infratentorial dura** (dura of the floor) has rich sensory innervation (hence very sensitive to pain). It is supplied by the following nerves:

1. **In anterior cranial fossa** – by the anterior and posterior ethmoidal nerves (and receives some twigs from the maxillary nerve).
2. **In middle cranial fossa** – by the meningeal branch of the maxillary nerve (in the anterior part) and the meningeal branch of the mandibular nerve (nervus spinosus) in the posterior part.
3. **In posterior cranial fossa** – by the meningeal branches of the vagus and hypoglossal nerves. These are the C1 and C2 fibres carried by the cranial nerves. The dura mater around the foramen magnum is directly supplied by the C2 and C3 cervical nerves.

### Intracranial dural venous sinuses

These are the various venous channels present in the cranial dura. They are formed in the following two ways:

1. By the separation of two layers of cranial dura
2. By the reduplication of the meningeal layer.

All the venous sinuses, except the inferior sagittal and straight sinuses, lie between the meningeal and endosteal layers of the dura mater ([Fig. 21.15](#)). The sinuses have thin walls and are lined by endothelium, which is continuous with that of veins. They drain blood from the brain and skull bones. The blood from dural venous sinuses is ultimately drained into internal jugular veins. Several of the sinuses communicate with the veins outside the skull, through emissary veins. The characteristic features of dural

venous sinuses are as follows.

**FIG. 21.15** ■ Intracranial dural venous sinuses and their connections (lateral view).

## Features

1. Lie between the layers of the dura mater
2. Have no muscle in their walls
3. Lined by endothelium only (muscular coat is absent)
4. Are devoid of valves in their lumen
5. Receive venous blood and CSF
6. Receive valveless emissary veins, which regulate the blood flow and maintain the equilibrium of venous pressure within and outside the skull.

## Classification

The dural venous sinuses are classified into two types: paired and unpaired ([Table 21.1](#)).

## TABLE 21.1

### Classification of paired and unpaired dural venous sinuses

Unpaired sinuses	Paired sinuses
1. Superior sagittal	1. Cavernous
2. Inferior sagittal	2. Superior petrosal
3. Straight	3. Inferior petrosal
4. Occipital	4. Transverse
5. Anterior intercavernous	5. Sigmoid
6. Posterior intercavernous	6. Sphenoparietal
7. Basilar venous plexus	7. Petrosquamous

#### N.B.

- The middle meningeal veins are often termed *middle meningeal sinuses*.
- The sigmoid and transverse sinuses together are often termed as *lateral sinus* by the clinicians.

#### Cavernous sinus (Fig. 21.16 )

These are paired sinuses.

**FIG. 21.16 ■** Cavernous sinuses as seen in the coronal section showing their relations and contents.

### **Location**

Each cavernous sinus (2 cm long, 1 cm wide) is a large venous space situated on either side of the body of the sphenoid and sella turcica in the middle cranial fossa. Its interior is divided into a number of small spaces (caverns) by trabeculae; hence, the name cavernous sinus. The floor of the sinus is formed by the endosteal layer, whereas the lateral wall, roof, and medial wall by the meningeal layer. Medially, the roof is continuous with the diaphragma sellae. Posteriorly, the roof has a triangular depression between attached margin (edge) of tentorium cerebelli to the posterior clinoid process and ridge raised by the free margin (edge) of tentorium cerebelli as it extends forward to gain attachment on anterior clinoid process. The oculomotor and trochlear nerves pierce this triangle to enter the cavernous sinus.

### **Extent**

Each sinus extends anteriorly up to the medial end of superior orbital fissure, and posteriorly, up to apex of the petrous temporal bone.

### **Relations**

#### **Superior**

1. Optic chiasma
2. Optic tract
3. Internal carotid artery
4. Anterior perforated substance

#### **Inferior**

1. Foramen lacerum
2. Junction of the body and the greater wing of the sphenoid

#### **Medial**

1. Pituitary gland (hypophysis cerebri)
2. Sphenoid air sinus

## **Lateral**

1. Temporal lobe (uncus) of the cerebral hemisphere
2. Cavum trigeminale containing the trigeminal ganglion

## **Anterior**

1. Superior orbital fissure
2. Apex of the orbit

## **Posterior**

1. Crus cerebri of midbrain
2. Apex of the petrous temporal bone.

## **Structures present in lateral wall of the sinus**

From above downward, these are as follows:

1. Oculomotor nerve
2. Trochlear nerve
3. Ophthalmic nerve
4. Maxillary nerve.

## **Structures passing through cavernous sinus**

1. *Internal carotid artery* is surrounded by the sympathetic plexus of nerves.
2. *Abducent nerve* (it enters the sinus by passing below the petrosphenoid ligament and accompanies the artery on its inferolateral aspect).

It is believed that the pulsations of the internal carotid artery help in expelling blood from the sinus.

## **Tributaries of the cavernous sinus (Fig. 21.17 )**

The cavernous sinus receives blood from three sources: orbit, meninges, and brain. Hence, its tributaries come from these sources as follows.

sagittal sinus

**FIG. 21.17 ■** Tributaries and communications of cavernous sinus (superior view). A, anterior intercavernous sinus; P, posterior intercavernous sinus; E, emissary vein.

### From orbit

1. Superior ophthalmic vein
2. Inferior ophthalmic vein
3. Central vein of retina (sometimes)

### From meninges

1. Sphenoparietal sinus
2. Anterior (frontal) trunk of the middle meningeal vein

### From brain

1. Superficial middle cerebral vein
2. Inferior cerebral veins (only few).

### Communications of cavernous sinus (Fig. 21.17 )

The cavernous sinus communicates with the:

1. Transverse sinus via superior petrosal sinus
2. Internal jugular vein via inferior petrosal sinus
3. Pterygoid venous plexus via emissary veins, which pass through foramen ovale, foramen lacerum, and emissary sphenoidal foramen
4. Facial vein via two routes:
  - (a) Superior ophthalmic vein → Angular vein → Facial vein
  - (b) Emissary veins → Pterygoid venous plexus → Deep facial vein → Facial vein
5. Opposite cavernous sinus via anterior and posterior intercavernous sinuses
6. Superior sagittal sinus via superficial middle cerebral vein and superior anastomotic vein with transverse sinus via superficial middle cerebral vein and inferior anastomotic vein.

7. Internal vertebral venous plexus, via basilar venous plexus.

## CLINICAL CORRELATION AN 30.4

- **Cavernous sinus thrombosis:** The septic thrombosis of cavernous sinus may be caused due to its numerous communications.

☞ The most common cause of thrombosis is the passage of septic emboli from the dangerous area of the face through facial vein → deep facial vein → pterygoid venous plexus → emissary vein.

☞ *Signs and symptoms:*

■ Cavernous sinus thrombosis gives rise to the following signs and symptoms:

- Severe pain in the eye and forehead, due to involvement of the ophthalmic nerve.
- Ophthalmoplegia (paralysis of ocular muscles) due to involvement of the 3rd, 4th, and 6th cranial nerves.
- Marked oedema of eyelids with exophthalmos, due to congestion of orbital veins following obstruction of ophthalmic veins.

- **Arteriovenous communication:** If the internal carotid artery is ruptured in the fracture base of the skull, an arteriovenous communication/fistula is established between the artery and cavernous sinus. Consequently, arterial blood rushes into the cavernous sinus, enlarging it and forcing blood into the connecting veins.

☞ *Signs and symptoms:*

■ Arteriovenous communication gives rise to the following signs and symptoms:

1. Pulsating exophthalmos; the eyeball protrudes and pulsates with each heartbeat.
2. A loud bruit (loud systolic murmur) is easily heard over the eye.
3. Ophthalmoplegia due to involvement of the 3rd, 4th, and 6th cranial nerves.
4. Marked orbital and conjunctival oedema due to raised venous pressure in the cavernous sinus.

## Superior sagittal sinus

It is an unpaired dural venous sinus. It lies between the two layers of the falx

cerebri along the convexity of its attached border (Fig. 21.18 ).

**FIG. 21.18** ■ Schematic coronal section through the superior sagittal sinus showing arachnoid granulations and absorption of the cerebrospinal fluid.

It begins at the crista galli behind the foramen caecum, passes backward (lodges itself in a sagittal groove on the vault of the skull) and on reaching the internal occipital protuberance, it deviates usually to the right to become continuous with the right transverse sinus, which, in turn, becomes continuous with the right sigmoid sinus. The right sigmoid sinus leaves the skull through the jugular foramen to continue as the right internal jugular vein. The size of sinus becomes progressively larger as it passes backward from the crista galli to the internal occipital protuberance.

## Features

1. Is triangular in cross-section
2. Communicates with venous lacunae on each side; the sites of drainage of diploic and meningeal veins
3. Arachnoid granulations project into its lumen (and those of venous lacunae).

## Tributaries

1. Superior cerebral veins
2. Parietal emissary veins
3. Small vein from the nasal cavity (if foramen caecum is patent)
4. Veins of the frontal air sinus.

## CLINICAL CORRELATION

**Thrombosis of superior sagittal sinus:** The spread of infection from dangerous area of the face, scalp, and diploë to the superior sagittal sinus may cause its thrombosis.

The presenting clinical features of thrombosis are as follows:

- (a) *Marked increase in intracranial pressure* , due to defective adsorption of CSF
- (b) *Delirium* due to congestion of superior cerebral veins.

## Inferior sagittal sinus

It is an unpaired dural venous sinus. It is a small venous channel present between the two layers of the lower free margin of the falx cerebri. It ends by joining the great cerebral vein to form straight sinus. It drains lower part of the medial surface of each cerebral hemisphere.

## Straight sinus

It is an unpaired dural venous sinus. It lies in the median plane within the junction of falx cerebri and tentorium cerebelli.

It begins as a continuation of the inferior sagittal sinus and terminates usually into the left transverse sinus, which at the mastoid angle of the parietal bone becomes continuous with the left sigmoid sinus.

## Transverse sinus

These are paired dural venous sinuses. Each sinus begins at the internal occipital protuberance and runs laterally between the two layers of the attached margin of the tentorium cerebelli. It courses horizontally grooving the occipital bone and mastoid angle of the parietal bone, and becomes continuous as the sigmoid sinus. The right transverse sinus is larger than the left transverse sinus because right sinus is the continuation of larger superior sagittal sinus and left sinus is the continuation of smaller straight sinus.

## Sigmoid sinus

These are paired dural venous sinuses. Each sigmoid sinus is a direct continuation of the transverse sinus. It is sigmoid or S-shaped, hence its name. In its course, it deeply grooves the inner surface of the mastoid part of the petrous bone. Its terminal part curves downward and then forward to the posterior margin of the jugular foramen through which it passes to continue as the internal jugular vein.

Its tributaries are as follows:

1. Mastoid and condylar emissary veins
2. Cerebellar veins
3. Internal auditory vein.

### CLINICAL CORRELATION

**Thrombosis of sigmoid sinus:** The sigmoid sinus is separated from the mastoid antrum and mastoid air cells only by a thin plate of the bone. The thrombosis of the sigmoid sinus is, therefore, secondary to infection of the middle ear or mastoid process. Furthermore, utmost care should be taken not to expose sigmoid sinus during operations on the mastoid process.

## Occipital sinus AN 30.4

It is an unpaired dural venous sinus and lies between the two layers of the attached margin of falx cerebelli. The occipital sinus runs downward from internal occipital protuberance to the posterior margin of the foramen magnum where it skirts the margin of the foramen and drains into the sigmoid sinuses.

### N.B.

*Confluence of sinuses (torcular Herophili):* It is the region where the superior sagittal and straight sinuses end and the right and left transverse sinuses begin. The occipital sinus also drains into the confluence. The confluence of sinuses is situated near the internal occipital protuberance.

## Sphenoparietal sinus AN 30.4

The sphenoparietal sinus lies along the posterior free margin of the lesser wing of the sphenoid and drains into anterior part of the cavernous sinus.

## Superior petrosal sinus AN 30.4

This sinus lies in the anterior part of the attached margin of tentorium cerebelli and crosses above the trigeminal nerve. It connects the coronal sinus with the transverse sinus.

### **Inferior petrosal sinus AN 30.4**

This sinus lies on either side in the petro-occipital suture. It emerges from cavernous sinus within middle cranial fossa and drains into internal jugular vein.

### **Petrosquamous sinus AN 30.4**

This sinus lies in the petrosquamous suture if present and drains into the transverse sinus.

### **Anterior and posterior intercavernous sinuses AN 30.4**

The anterior and posterior intercavernous sinuses connect the cavernous sinuses. They pass through diaphragma sellae in front and behind the opening for infundibulum of the pituitary gland, respectively. Intercavernous sinuses and cavernous sinuses together form the circular dural venous sinus.

## **Other dural venous sinuses**

### **Basilar venous plexus**

It consists of network of veins lying between the endosteal and meningeal layers of dura on the clivus. It connects the two inferior petrosal sinuses and communicates with the internal vertebral venous plexus. It receives blood from the pons and medulla. Thrombosis of the basilar venous plexus is, therefore, usually fatal.

This plexus is included in the group of unpaired dural venous sinuses.

### ***Middle meningeal veins :***

They are one on each side. Each forms two trunks: frontal and parietal. These are sometimes called as middle meningeal sinuses. The two trunks follow the corresponding divisions of the middle meningeal artery nearer to the bone, hence more liable to injury in skull fracture. The frontal trunk usually drains into the cavernous sinus and the parietal trunk into the pterygoid venous plexus by passing through the foramen spinosum.

## **Pituitary gland**

The pituitary gland (hypophysis cerebri) has been described in detail in *General Anatomy, with Systemic Anatomy, Radiological Anatomy, Medical Genetics*, 4ed. by Vishram Singh (pages 182–184). The following text deals with the surgical anatomy of the gland.

### Location (Fig. 21.19 )

The pituitary gland is a small endocrine gland situated in the hypophyseal fossa on the superior surface of the body of the sphenoid (*sella turcica*). It is suspended from the floor of the third ventricle of the brain by a narrow stalk called **infundibulum**. The gland is enclosed in the dural sheath, whose tense upper wall – the **diaphragma sellae** – is perforated by the infundibulum or stalk. On each side, the pituitary gland is related to the cavernous sinus in front and behind to the anterior and posterior intercavernous sinuses.

**FIG. 21.19** ■ Location of hypophysis cerebri (pituitary gland).

### Shape and measurements

The gland is oval in shape and measures 8 mm anteroposteriorly, 12 mm transversely, and weighs approximately 500 mg.

## Relations

<i>Superior</i>	Optic chiasma with diaphragma sella intervening
<i>Inferior</i>	Sphenoidal air sinuses with thin bony plate of the hypophyseal fossa intervening
<i>Lateral</i>	Cavernous sinus on each side.

## Subdivisions (Fig. 21.20 )

The gland has two main subdivisions: adenohypophysis and neurohypophysis, which differ from each other embryologically, morphologically, and functionally (Table 21.2 ). The **adenohypophysis** develops as a diverticulum (Rathke's pouch) from the ectodermal roof of the stomodeum. Normally, the communication with the roof of the pharynx disappears completely owing to the rapid growth of the sphenoid. Occasionally, however, it may persist as a *craniopharyngeal canal* . The uppermost part of the original diverticulum remains as a cleft, which separates the pars anterior and pars intermedia. The **neurohypophysis** develops as a downgrowth from the floor of the diencephalon.

*Adenohypophysis consists of:*

- (a) Pars anterior (pars distalis)
- (b) Pars intermedius
- (c) Pars tuberalis

*Neurohypophysis consists of:*

- (a) Pars posterior
- (b) Infundibulum.

**FIG. 21.20** ■ Parts of hypophysis cerebri as seen in sagittal section.

## **TABLE 21.2**

### **Hormones secreted by different parts of adenohypophysis**

Parts	Cell types/nuclei	Hormones secreted
Pars anterior	Acidophil cells	I. Growth hormone II. Prolactin
	Basophil cells	I. Adrenocorticotrophic hormone II. Thyrotrophic hormone III. Gonadotrophic hormone
Pars	Colloid containing vesicles of	Melanocyte-stimulating

intermedia	basophil cells	hormone
Pars posterior	Supraoptic nucleus of hypothalamus Paraventricular nucleus of hypothalamus	Vasopressin or antidiuretic hormone Oxytocin

## Functional connections with hypothalamus

### Hypothalamo-hypophysial tract

It consists of nerve fibres arising from the supraoptic and paraventricular nuclei of the hypothalamus and projecting into the posterior lobe of the pituitary gland. The vasopressin and ADH produced in supraoptic and paraventricular nuclei are transported by the nerve fibres of the tract, and stored in the nerve terminals (**Herring bodies**) of these fibres in the posterior lobe (neurohypophysis). Then hormones are released in the venous sinusoids as and when necessary.

### Hypothalamo-hypophysial portal system

It consists of two sets of capillaries: one in the hypothalamus (**median eminence**) and other in the hypophysis cerebri (sinusoids of pars anterior). The neurons of the hypothalamus produce hormone-releasing factors in the capillaries of the median eminence and upper part of the infundibulum. These are carried by the portal system to pars anterior where they stimulate it to release appropriate hormones.

### Arterial supply (**Fig. 21.21**)

The following branches of internal carotid artery supply the pituitary gland:

1. Superior hypophyseal artery, one on each side
2. Inferior hypophyseal artery, one on each side.

**FIG. 21.21 ■** Blood supply of pituitary gland. Note the hypothalamo-hypophyseal connections.

### **Venous drainage (Fig. 21.21 )**

Short veins from the pituitary gland drain into neighbouring dural venous sinuses (e.g., cavernous and intercavernous sinuses). The hormones pass out of the gland through venous blood to the target sites.

### **Microanatomy of pituitary gland (Fig. 21.22 ) AN 43.2**

- The anterior lobe mainly consists of two types of secretory cells, i.e., acidophils (43%) and basophils. They contain granules and stained by

acidic dye, i.e., eosin, and basic dye, i. e., haematoxylin repetitively.

- The **pars intermedia** consists of colloid filled small vesicles lined by basophils and acidophils.
- The pars posterior consists of unmyelinated nerve fibres, Herring bodies (are dilated terminals of nerve fibres containing hormones), and pituicytes (purple-stained glial cells).

**FIG. 21.22** ■ Microscopic structure of pituitary gland.

The hormones secreted by different parts of adenohypophysis are given in Table 21.2 .

### CLINICAL CORRELATION AN 30.5

- **Craniopharyngioma:** The remnants of Rathke's pouch may give rise to a tumour inside the sphenoid bone called *craniopharyngioma*. Sometimes some cells of Rathke's pouch extend backward along the

roof of the nasopharynx and form an accessory lobe of the anterior lobe in the pharyngeal wall called *pharyngeal hypophysis* .

- **Pituitary tumours:** The pituitary tumours occur commonly. The most common tumour of the pituitary gland is *adenoma* arising from its chromophobe cells. Pituitary adenoma produces two types of symptoms: (a) symptoms because of pressure on adjacent structures, and (b) symptoms because of endocrine disturbances.

***Symptoms because of pressure on adjacent structures:***

- *Enlargement of hypophyseal fossa* due to downward growth (intrasellar growth) of an adenoma. It is seen as ballooning of hypophyseal fossa (sella turcica) in plane radiograph of skull (lateral view).
- *Bitemporal hemianopia/tunnel vision* (loss of vision in right and left temporal fields of vision) due to the upward growth of adenoma pressing the central part of the optic chiasma (Fig. 21.23 ).
- *Exophthalmos and ophthalmoplegia* due to pressure on the cavernous sinus.

***Symptoms because of endocrine disturbances:***

- *Gigantism* before puberty and *acromegaly* in adults, due to excessive secretion of growth (GH) hormone.
- *Cushing syndrome* due to excessive secretion ACTH.
- *Dwarfism* due to hyposecretion of GH in infants and children due to involvement of the anterior lobe.
- *Diabetes insipidus* due to involvement of the posterior lobe.

***Surgical approaches for removal of pituitary adenoma:*** The pituitary tumours may be removed by the transfrontal operation or by the trans-sphenoidal route.

❖(a) *Trans-sphenoidal approach:* In this approach, the surgeon enters the pituitary fossa from below through a sphenoidal air sinus, either via ethmoidal cells after raising the periosteum from the medial wall of the orbit (actually it should be termed as transorbital–transethmoidal–trans-sphenoidal approach) or by elevating the nasal mucosa from the nasal septum and removing the nasal septum (note that nasal cavity itself is not entered) and rostrum of the sphenoid (*transnasal –trans-sphenoidal approach* ).

❖(b) *Transfrontal (subfrontal) approach:* In this, the gland is

approached through the anterior cranial fossa by elevating the frontal lobe of the brain.

**FIG. 21.23** ■ Bitemporal hemianopia (tunnel vision). T, temporal field of vision; N, nasal field of vision.

### **Golden Facts to Remember**

• <b>Largest bony cavity in the body</b>	Cranial cavity
• <b>Deepest cranial fossa</b>	Posterior
• <b>Largest bony foramen in the body</b>	Foramen magnum
• <b>Most common site of fracture of the base of skull</b>	Middle cranial fossa
• <b>All dural venous sinuses</b>	Inferior sagittal and straight sinuses

lie between meningeal and endosteal layers of the dura mater except	
• Longest dural venous sinus	Superior sagittal sinus
• Chief source of blood supply to the skull bone	Meningeal vessels
• Commonest tumours of the pituitary gland	Adenoma arising from its chromophobe cells
• Rathke's pouch	Ectodermal diverticulum from roof of stomodeum giving rise to adenohypophysis
• Herring bodies	Distended nerve terminals of hypothalamo-hypophyseal tracts containing oxytocin and vasopressin, and antidiuretic hormones
• Commonest cause of extradural haematoma	Tear of the anterior trunk of middle meningeal vein and anterior branch of middle meningeal artery
• Meckel's cave	Pouch of inner layer of the dura mater over trigeminal impression on anterior surface of the petrous temporal bone containing the trigeminal ganglion
• Largest diploic vein	Occipital diploic vein

## CLINICAL CASE STUDY

A 49-year-old man fell from the second-floor terrace of his house. He became unconscious and there was bleeding from his head. He was immediately taken to the nearby hospital, where on examination, the doctors found that his occipital region was badly bruised. They also noticed bleeding from his right ear. On careful examination, it was noticed that his right eye was protruded and pulsating. The conjunctiva was engorged (chemosis). A CT scan revealed the **fracture of the base of the skull in the region of middle cranial fossa** .

### Questions

1. What is the commonest site of fracture of the base of the skull?  
Mention the reason(s) for the same.

2. Why is fracture of middle cranial fossa often associated with bleeding from the ear?
3. What is the anatomical basis of pulsations in the right eye?

### Answers

1. Middle cranial fossa because the base of the skull in this region is weak because of the presence of a large number of foramina and canals.
2. In fracture of middle cranial fossa, the roof of middle ear (tegmen tympani) is fractured and the tympanic membrane is torn, which results in bleeding from the ear.
3. If internal carotid artery within cavernous sinus is torn in fracture, there occurs an arteriovenous fistula. The blood from the artery because of high arterial pressure rushes into the cavernous sinus, forcing the blood of cavernous sinus into the ophthalmic veins. As a result, the eye protrudes (exophthalmos) and the conjunctiva becomes engorged. The bulging eye pulsates (pulsating exophthalmos) in synchrony with the arterial pulse.

---

# Chapter 22: Cranial nerves

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Give anatomical basis of signs and symptoms to oculomotor, trochlear, and abducent nerve palsies along with strabismus. **AN 31.5**
- Describe abducent, facial, glossopharyngeal, and hypoglossal nerves under the following headings: (a) functional components, (b) origin and course, (c) branches and distribution, and (d) applied anatomy.
- Give anatomical basis of: (a) trigeminal neuralgia (tic douloureux), (b) squint, (c) Bell palsy, (d) gag reflex, and (e) Ipsilateral deviation of tongue in hypoglossal nerve lesion.
- Write short notes on: (a) distribution of oculomotor nerve, (b) trochlear nerve, and (c) unique features of optic nerve.
- Explain anatomical basis of hypoglossal nerve palsy. **AN 39.2**

There are 12 pairs of the cranial nerves; of which, first 2 pairs arise from the **forebrain** and the next 10 pairs arise from the **brainstem**. They are numbered 1–12 in the craniocaudal sequence of their attachment on the brain. The cranial nerves are generally designated by Roman numerals.

The 12 pairs of cranial nerves are as follows:

I	Olfactory	VII	Facial
II	Optic	VIII	Vestibulocochlear
III	Oculomotor	IX	Glossopharyngeal
IV	Trochlear	X	Vagus
V	Trigeminal	XI	Accessory
VI	Abducent	XII	Hypoglossal

## N.B.

- A minute bundle of nerve fibres closely related to the olfactory nerves is termed the *nervi terminalis* or '*O*' (*Zero*) *pair of cranial nerves* . Each nerve is attached to the cerebrum, posterior to the olfactory stria of the olfactory tract close to anterior perforated substance and septal areas and distributed to the nasal mucous membrane. Its exact function is not known, but it is thought to provide a special chemosensory pathway of olfaction and affects the secretion of luteinizing hormone-releasing factor from the hypothalamus. In addition, it plays an important role in smell-mediated sex behaviour.

## Functional components

A cranial nerve consists of motor fibres (**motor nerve** ) or sensory fibres (**sensory nerve** ), or both the motor and sensory fibres (**mixed nerve** ).

The ***motor fibres of cranial nerves*** can be of the following three types:

1. Somatic efferent (SE) or general somatic efferent (GSE) fibres. They supply the striated muscles, which develop from somites.
2. **Special visceral efferent (SVE) fibres.** They supply the muscles that develop from the mesoderm of pharyngeal arches.
3. **General visceral efferent (GVE) fibres.** They supply the glands, smooth muscles of viscera, and vessels. They are preganglionic parasympathetic fibres.

The ***sensory fibres of cranial nerves*** can be of the following four types:

1. **General somatic afferent (GSA) fibres.** They carry general sensations of pain, touch, and temperature from skin and proprioceptive sensations of vibration and muscle and joint sense.
2. **General visceral afferent (GVA) fibres.** They carry general sensations of distension and ischaemic pain from viscera.
3. **Special visceral afferent (SVA) fibres.** They carry special sensations of taste from tongue.

In addition to the aforementioned three types, the sensory fibres may be **special somatic afferent (SSA)** , which carry special sensations of *smell* , *hearing* , and *balance* .

## N.B.

- The *motor fibres of cranial nerves* arise as outgrowths of axons from motor nuclei situated within the central nervous system (CNS).
- The *sensory fibres* arise as outgrowths of axons from cells situated within the sensory ganglia (situated outside the CNS) and terminate in the sensory nuclei situated within the CNS.
- The *motor and sensory nuclei* within the CNS are arranged in longitudinal columns called functional columns.

## Olfactory nerve

Olfactory nerve is the 1st cranial nerve. It is purely sensory and carries the sense of smell from nasal cavity (Fig. 22.1 ).

**FIG. 22.1** ■ Olfactory nerve and location of olfactory epithelium in the nasal cavity.

## Unique features

1. The primary sensory neurons of olfactory nerve lie on the body surface in the epithelial lining of the nasal cavity and their dendrites lie free in the mucous film.
2. The primary sensory neurons of olfactory nerve (olfactory neurons) undergo continuous turnover, i.e., they are continuously replaced by

stem cells in the olfactory neuroepithelium.

### Functional component

**SSA fibres:** They carry special sensations of smell from the olfactory region of the nasal cavity and terminate in the olfactory bulb.

### Course, relations, and distribution

Each olfactory nerve consists of approximately 20 minute bundles of nonmyelinated nerve fibres. They arise from primary receptor neurons (modified bipolar neurons) of the olfactory epithelium of nasal cavity, pass through foramina in the cribriform plate of the ethmoid to enter the anterior cranial fossa, where they terminate in the olfactory bulb. In the olfactory bulb, they synapse with the mitral cells. The bundles of olfactory nerves are surrounded by three meninges (namely, pia mater, arachnoid mater, and dura mater) near the cribriform plate. This provides a potential communication between the subarachnoid space and lymphatics of the nasal mucosa. Thus, infection from nose can spread into the meninges of the brain.

*Distribution :* **olfactory region of the nasal cavity.**

### CLINICAL CORRELATION

- **Anosmia:** The loss of sense of smell is called *anosmia*. Anosmia can occur for a number of reasons such as atrophic rhinitis (degenerative disorder of nasal mucosa) and fracture of the anterior cranial fossa (ethmoidal fracture). The ethmoidal fracture is often associated with blood-stained cerebrospinal fluid (CSF rhinorrhoea).
- **Clinical testing of olfactory nerve:** The olfactory nerve is tested clinically by asking the patient to smell common odours, such as peppermint, garlic, or cloves from each side of his or her nostril separately with eyes closed.

### Optic nerve

Optic nerve is the 2nd cranial nerve. It is purely sensory and responsible for vision; hence, it is also called the **nerve of sight**. This nerve transmits special afferent impulses of light to the brain.

### Unique features

The optic nerve is not a true peripheral (cranial) nerve. It is actually a tract of

brain for it develops as an outgrowth of diencephalon during embryonic life. Hence, it presents the following unique features:

1. It consists of second-order sensory neurons.
2. Its fibres are myelinated by oligodendrocytes.
3. It is surrounded by meninges.
4. Its fibres cannot regenerate if cut/damaged.

### Functional component

**SSA fibres:** They carry sense of sight from the visual field of the corresponding eye.

### Course, relations and distribution

The fibres of optic nerve arise from ganglion cells (second-order neurons) in the neural layer of the retina of the eyeball, converge towards the optic disc at the posterior pole of the eyeball, pierce the outer layer of retina, choroid, and sclera to leave the eyeball. Immediately after emerging from the eyeball, the fibres unite to form the optic nerve, which passes posteromedially through the posterior half of the orbit and enter the middle cranial fossa through the optic canal. In the middle cranial fossa, optic nerves of two sides unite to form the **optic chiasma**. The mid-region of optic chiasma is composed of crossed fibres from the medial/nasal halves of the retina of both eyes, whereas the lateral region is made up of fibres from lateral/temporal half of the retina of the ipsilateral eye.

Diverging from the chiasma are the optic tracts. Most of the fibres of the optic tract relay in the lateral geniculate body. The third-order neurons arise in the lateral geniculate body, run in the retrolenticular part of the internal capsule, and form optic radiations. The fibres of optic radiation terminate in and around the calcarine sulcus of the occipital lobe (visual cortex). Some of the fibres from the lateral geniculate body reach the pretectal area of the midbrain and form a part of the pathway for **light reflex**.

Thus, **optic pathway** consists of the following components ([Fig. 22.2](#)):

*Retina → optic nerve → optic chiasma → optic tract → lateral geniculate body → optic radiation → visual cortex*

**FIG. 22.2 ■** Basic components of the visual pathway.  
EW, Edinger–Westphal nucleus.

## Parts of optic nerve

The optic nerve is 4 cm in length. It is divided into three parts: (a) *intra-orbital part*, (b) *canalicular part*, and (c) *intracranial part*.

It is enclosed by three meninges of the brain. The thick fibrous dural sheath of optic nerve blends with the sclera of the eyeball. The subarachnoid space containing CSF surrounds the optic nerve and is continuous with the subarachnoid space of the brain (see [Fig. 19.25](#)).

## CLINICAL CORRELATION

- **Ipsilateral total blindness:** It may occur because of damage of optic nerve or blockage of central artery of retina. The compression of optic nerve results in *optic atrophy*, which subsequently leads to ipsilateral total blindness called *anopia*.
- **Papilloedema:** The central vein of retina is enclosed in the meninges of the anterior part of optic nerve which is surrounded by CSF in the subarachnoid space. Therefore, an increased CSF pressure within the cranial cavity impedes the return of venous blood from the retina by pressing the central vein of retina and its tributaries. This results in swelling of optic disc owing to oedema called *papilloedema*. The papilloedema is a valuable clinical evidence of an increased intracranial pressure.
- **Clinical testing of optic nerve:** The optic nerve is tested clinically by performing tests for visual acuity, colour perception, and loss of vision in different visual fields.

## Oculomotor nerve

Oculomotor nerve is the 3rd cranial nerve. It is purely motor. As its name implies, it **moves the eye**. It supplies most of the muscles of the eye and plays a principal role in accommodation of the eye.

## Functional components and nuclei ([Fig. 22.3](#))

1. **GSE fibres:** They supply all extraocular muscles except lateral rectus (supplied by 6th cranial nerve) and superior oblique (supplied by 4th cranial nerve); *mnemonic*: A3, LR6So4.
  - The GSE fibres **arise from the somatic component of oculomotor nucleus** (also called the somatic motor nucleus).

2. **GVE fibres:** They supply the sphincter pupillae and ciliaris muscles.
- They **arise from the parasympathetic component of oculomotor nucleus** (also called the Edinger–Westphal nucleus). These are preganglionic parasympathetic fibres and relay in the ciliary ganglion. The postganglionic parasympathetic fibres arise from the ganglion and supply the sphincter pupillae and ciliaris muscles.

**FIG. 22.3 ■** Oculomotor nerve. (A) The functional components and nuclei of the oculomotor nerve; (B) the distribution of the constitutional fibres of the oculomotor nerve.

### Course, relations, and distribution (Fig. 22.4 )

The oculomotor nerve arises from the **oculomotor sulcus** on the medial aspect of the cerebral peduncle of the midbrain and appears in the interpeduncular fossa. It runs forward and laterally between the posterior cerebral and superior cerebellar arteries and lateral to the posterior communicating artery, passes through the tentorial notch of tentorium cerebelli to reach the middle cranial fossa. Here, it pierces the dura mater in the **oculomotor triangle** lying in between the free and attached margins of tentorium cerebelli in the roof of the cavernous sinus and enters the lateral wall of the cavernous sinus, where it lies superior to the trochlear, ophthalmic, and maxillary nerves, and lateral to the internal carotid artery. In anterior part of the cavernous sinus, the nerve divides into upper and lower

divisions. The two divisions enter the orbit through the superior orbital fissure within the common tendinous ring. The nasociliary nerve intervenes between the two divisions. The smaller upper division passes above the optic nerve on the inferior surface of superior rectus (which it supplies), and then passes through the superior rectus to supply the levator palpebrae superioris. The larger lower division passes below the optic nerve and immediately gives three branches, which supply the medial rectus, inferior rectus, and inferior oblique muscles.

**FIG. 22.4 ■** Origin, course, and distribution of the oculomotor nerve.

The larger inferior division of the oculomotor nerve passes below the optic nerve and immediately gives three branches, which supply the medial rectus, inferior rectus, and inferior oblique muscles. The nerve to inferior oblique

gives motor root (parasympathetic root) to the ciliary ganglion located in the posterior part of the orbit. The postganglionic fibres from this ganglion run through short ciliary nerves and supply the sphincter pupillae and ciliaris muscles.

## CLINICAL CORRELATION

**Lesions of oculomotor nerve AN 31.5 :** The damage of oculomotor nerve may occur because of the following factors:

- (a) *Microvascular infarction* is usually caused by diabetes mellitus, hypertension, etc.
- (b) *Compression by aneurysm of the internal carotid artery* as it passes through the lateral wall of the cavernous sinus.
- (c) *Compression by transtentorial uncal herniation* as it passes through the tentorial notch.

### **Lesions of oculomotor nerve clinically presents as:**

- *Ptosis* (drooping of the upper eyelid), due to paralysis of the levator palpebrae superioris.
- *Lateral strabismus (i.e., lateral squint)*, due to paralysis of the medial rectus and consequent unopposed action of the lateral rectus muscle.
- *Dilated and fixed pupil*, due to paralysis of the sphincter pupillae and consequent unopposed action of the dilator pupillae.
- *Loss of accommodation*, due to paralysis of the medial rectus, sphincter pupillae, and ciliaris muscles.
- *Double vision or diplopia occurs on* looking medially, inferiorly, and superiorly due to paralysis of the medial rectus, inferior rectus, and inferior oblique muscles.
- *Proptosis* (prominence of the eyeball) due to relaxation of the muscles of the eyeball.

## **Trochlear nerve AN 31.5**

Trochlear nerve is the 4th cranial nerve. It is purely motor and supplies only one muscle – the superior oblique muscle of the eyeball.

### **Unique features**

1. It is the only cranial nerve that emerges on the dorsal aspect of the brain.
2. It is the slenderest of all the cranial nerves.
3. It is the smallest cranial nerve.
4. It is the only cranial nerve whose nuclear fibres decussate before emerging on the surface of the brain.
5. Its nucleus receives contralateral corticonuclear fibres.
6. Phylogenetically, it is the nerve of 3rd eye.

### **Functional components and nuclei**

**GSE fibres:** They arise from the trochlear nucleus in the midbrain and supply the superior oblique muscle of the eyeball.

### **Course, relations, and distribution (Fig. 22.5 )**

The trochlear nerves arise from the dorsal aspect of the midbrain, one on either side of **frenulum veli** . After emerging from the brain, the nerve winds round the superior cerebellar peduncle and cerebral peduncle just above the pons. It then passes between the posterior cerebral and superior cerebellar arteries to appear ventrally. It lies medial to and below the free margin to tentorium cerebelli. The nerve enters the cavernous sinus by piercing the posterior corner of its roof. In the cavernous sinus, it runs forward in its lateral wall between the oculomotor and ophthalmic nerves. In the anterior part of the sinus, it crosses over the oculomotor nerve and becomes lateral to it. The nerve enters the orbit through the superior orbital fissure superolateral to the tendinous ring. It runs medially above the levator palpebrae superioris to enter the orbital surface of the superior oblique, which it supplies.

**FIG. 22.5** ■ Origin, course, and distribution of the trochlear nerve.

## CLINICAL CORRELATION

**Lesions of trochlear nerve AN 31.5 :** The injury of trochlear nerve will cause paralysis of the superior oblique muscle of the eyeball.

This will clinically present as:

- (a) *Extorsion of the eyeball and weakness of downward gaze* . As a result, the patient faces difficulty while going downstairs or reading newspaper.
- (b) *Diplopia* (double vision), which occurs when the patient looks laterally and in glances on looking downward. There is compensatory head-tilting

to the opposite side.

(c) *Paralytic vertical strabismus (squint)* .

## Abducent nerve AN 31.5

Abducent nerve is the 6th cranial nerve. It is purely motor and supplies only one muscle – the lateral rectus of the eyeball. It is so named because it abducts the eye. It is also called lover's nerve, because in ancient times (nonverbal era between the teenager girls and boys), the boy used to call the girls from a gathering by sending signal through the action of this muscle.

### Unique feature

It is most susceptible to damage of all the cranial nerves during increased intracranial pressure.

### Functional components and nuclei

- **GSE fibres.** They arise from the abducent nucleus in the pons and supply the lateral rectus muscle of the eyeball.

### N. B.

**GSA fibres.** The 3rd, 4th and 6th cranial nerve nuclei also carry GSA fibres from extraocular muscles. They carry proprioceptive sensations and terminate in the mesencephalic nucleus of the trigeminal nerve.

### Course, relations, and distribution (Fig. 22.6 )

The abducent nerve arises at the lower border of the pons opposite the pyramid of the medulla. The nerve runs upward, forward, and laterally dorsal to the anterior inferior cerebellar artery in the subarachnoid space and pierces the dura mater over the clivus inferolateral to the dorsum sellae. It then passes deep to the inferior petrosal sinus and arches forward directly over the sharp ridge of the petrous temporal bone, under the **petroclinoid ligament** and enters the fibro-osseous canal (**Dorello's canal** ) formed by the apex of the petrous temporal bone and petroclinoid ligament (**Gruber's ligament** ). The nerve then enters the cavernous sinus by piercing the posterior wall close to the floor of the sinus. In the cavernous sinus, it runs forward inferolateral to the internal carotid artery.

**FIG. 22.6 ■** Origin, course, and distribution of the abducent nerve.

The nerve enters the orbit through the superior orbital fissure within the tendinous ring lateral to two divisions of oculomotor and nasociliary nerves. In the orbit, it runs forward, towards the lateral side to enter the orbital surface of the lateral rectus muscle, which it supplies.

### CLINICAL CORRELATION

**Lesions of abducent nerve AN 31.5 :** The abducent nerve is generally damaged during increased intracranial pressure. During increased

intracranial pressure, the nerve is stretched because of the descent of brainstem. Consequently, the nerve is cut by the sharp bony edge of the petrous temporal bone.

The paralysis of lateral rectus muscle following the injury to the abducent nerve leads to:

- (a) *Convergent squint* due to the unopposed action of medial rectus
- (b) Inability to abduct the eye
- (c) *Diplopia* (double vision) with maximum separation of two images while looking towards the paralysed side.

## **Strabismus/squint**

The strabismus is a condition in which two eyes are misaligned, i.e. two eyes point in different directions.

If one eye turns inwards it is called as *convergent squint*, if it turns outward, it is called *divergent squint* and if it turns up or down, it is called *vertical squint* ([Fig. 22.7](#)).

**A 3rd nerve lesion**

**B 4th nerve lesion**

**C 6th nerve lesion**

**FIG. 22.7** ■ Different types of strabismus/squint caused by the lesions of left 3rd (A), 4th (B) and 6th (C) cranial nerves, respectively.

Out of 12 cranial nerves only 3rd, 4th and 6th cranial nerves cause strabismus.

## Trigeminal nerve AN 31.5

Trigeminal nerve is the 5th cranial nerve. It is a mixed nerve containing both motor and sensory fibres but predominantly it is sensory. It consists of three large nerves: **ophthalmic**, **maxillary**, and **mandibular**, hence the name trigeminal nerve (Latin, *trigeminus* = triplet). It is a motor nerve to the muscles of mastication and several small muscles and the principal sensory nerve of the head and face.

### Unique features

1. It is the largest cranial nerve.
2. Its sensory ganglion (largest in the body) is located within the cranial cavity (cf. all the sensory ganglia are located outside the cranial cavity).

### Functional components and nuclei (Fig. 22.8 A)

1. **SVE fibres:** They arise from motor nucleus of the trigeminal nerve in the pons and supply the muscles derived from the 1st pharyngeal arch, i.e., the muscles of mastication, mylohyoid, anterior belly of digastric, tensor palati, and tensor tympani.
2. **GSA fibres:**
  - (a) They carry *exteroceptive sensations* (i.e., pain, touch, and temperature) from skin of head and face, mucous membrane of mouth, nasal cavity, meninges, etc., and terminate in the **main sensory nucleus and spinal nucleus of the trigeminal nerve**.
  - (b) They also carry *proprioceptive sensations* from the muscles of mastication, temporomandibular joint, and teeth and terminate in the **mesencephalic nucleus of the trigeminal nerve** and the reticular formation of brainstem.
    - ¶ The exteroceptive neurons are pseudounipolar and their cell bodies are located in the **trigeminal ganglion**.
    - ¶ The proprioceptive neurons are unipolar and their cell bodies are located in the **mesencephalic nucleus of the trigeminal nerve**.
    - ¶ *The mesencephalic nucleus is the only site in the CNS which contains unipolar neurons/first-order sensory neurons.*

### Course, relations, and distribution

The trigeminal nerve arises by two roots (a smaller medial motor root and a larger lateral sensory root) from the ventrolateral aspect of the pons at its junction with the middle cerebellar peduncle (Fig. 22.8 B).

**FIG. 22.8 ■ Trigeminal nerve.** A. Functional components of the trigeminal nerve. B. Roots and divisions of the trigeminal nerve, TG = trigeminal ganglion.

The sensory root passes forward and laterally over the apex of the petrous temporal bone to enter the middle cranial fossa. Here, it exhibits a rounded enlargement, the **trigeminal (gasserian) ganglion**. The ganglion occupies a dural invagination in a shallow fossa on the anterior surface of the petrous temporal bone.

The subarachnoid expansion over this portion of trigeminal nerve is called **Meckel's cave** ( Fig. 21.14 ). The sensory root may be cut here to relieve the pain of trigeminal neuralgia.

The convex distal surface of ganglion gives origin to three large divisions of the trigeminal nerve – ophthalmic, maxillary, and mandibular.

1. The **ophthalmic nerve** (purely sensory) arises from the anterolateral aspect of the ganglion and enters the lateral wall of the cavernous sinus where it lies below the trochlear nerve.
  - In the cavernous sinus, it divides into three branches: nasociliary, lacrimal, and frontal. All these branches enter the orbit through the superior orbital fissure.
2. The **maxillary nerve** (purely sensory) arises from the ganglion and enters the lateral wall of the cavernous sinus where it occupies the lowest position and leaves the cavernous sinus to enter the **pterygopalatine fossa** through the **foramen rotundum**.
3. The **mandibular nerve** (the largest division) arises from the trigeminal ganglion and immediately enters the infratemporal fossa through the foramen ovale.

The **motor root** of the trigeminal nerve after emerging from the pons passes forward and laterally deep to the sensory root and trigeminal ganglion and enters the infratemporal fossa through the foramen ovale. After emerging from the foramen ovale, it immediately joins the mandibular nerve and thus the mandibular nerve contains both the motor and sensory fibres.

The ophthalmic division of the trigeminal nerve is described in detail in [Chapter 19](#) and maxillary and mandibular divisions in [Chapter 10](#).

**Distribution (Fig. 22.9):** The summary of distribution of the three divisions of the trigeminal nerve is presented in [Table 22.1](#).

**FIG. 22.9 ■** Trigeminal nerve. (A) Divisions and branches; (B) cutaneous distribution. AE, anterior ethmoidal; IT, infratrochlear; PE, posterior ethmoidal; SO, supraorbital; ST, supratrochlear; V1, ophthalmic division; V2, maxillary division; V3, mandibular division; 1, ciliary ganglion; 2, pterygopalatine ganglion; 3, otic ganglion; 4, submandibular ganglion. Z, Zygomatic branch.

## Summary of distribution of three divisions of the maxillary nerve

Nerve/division Distribution	
Ophthalmic (sensory)	Upper third of the face including eyeball, conjunctiva, nasal cavity, lacrimal gland, scalp up to vertex. Ophthalmic nerve also forms the afferent limb of <i>corneal reflex</i> .
Maxillary (sensory)	Middle third of the face including most of nasal cavity, upper teeth and gums, maxillary sinus, mucous membrane of naso pharynx, palate. Maxillary nerve conveys secretomotor fibres to the lacrimal gland and the glands of palate, nose, and oral cavity.
Mandibular (mixed)	<i>Sensory</i> : Lower third of the face (except small area over the angle of mandible) including part of auricle, temple and dura mater of middle cranial fossa. <i>Motor</i> : Muscles of mastication, mylohyoid, anterior belly of digastric, tensor palati, and tensor tympani. Mandibular nerve forms both the limbs of <b>masticatory reflex</b> .

### CLINICAL CORRELATION

**Trigeminal neuralgia ( *tic douloureux* )**: It is a clinical condition that presents a paroxysmal episodes of severe pain of sudden onset and short duration in the area of distribution of one or more of the three divisions of the trigeminal nerve in face.

The ophthalmic division (CN V<sub>1</sub>) is not commonly involved. The most commonly trigeminal neuralgia is associated with maxillary (CN V<sub>2</sub>) and mandibular divisions (CN V<sub>3</sub>) of the trigeminal nerve. It is often associated with dental caries.

## Facial nerve

Facial nerve is the 7th cranial nerve. It is a mixed (i.e., motor and sensory) nerve, but predominantly it is motor. It is named facial nerve because it supplies the muscles of facial expression. *It is the most frequently paralysed of all the peripheral nerves of the body.*

### Functional components and nuclei (Fig. 22.10 )

1. **SVE fibres.** They arise from the motor nucleus of the facial nerve in the pons and supply the muscles of facial expression.
2. **GVE fibres.** These are preganglionic parasympathetic fibres that arise from lacrimal and superior salivatory nuclei in the brainstem. They supply the secretomotor fibres to lacrimal, submandibular, and sublingual glands.
3. **SVA fibres.** They carry special sensations of taste from anterior two-third of the tongue except vallate papillae and terminate in the nucleus of tractus solitarius (gustatory nucleus) in the brainstem.
4. **GSA fibres.** They carry general sensations from the skin of the auricle and terminate in the spinal nucleus of the trigeminal nerve.

**FIG. 22.10** ■ Functional components and nuclei of the facial nerve.

The cell bodies of SVA and GVA fibres are located in the geniculate ganglion.

### Course and relations (Fig. 22.11)

This nerve consists of two distinct roots: (a) a large medial motor root (the *facial nerve proper*) and (b) a small lateral sensory root (the *nervus intermedius*). The two roots arise from the pontomedullary junction lateral to the superior end of the olive of the medulla. The sensory root lies between the motor root of facial medially and the vestibulocochlear nerve laterally.

**FIG. 22.11** ■ Origin, course, and distribution of the facial nerve. SP, sympathetic plexus around internal carotid artery. (A,B,C,D – Various levels of infranuclear lesions of facial nerve – See Clinical Correlation)

After emerging from the brainstem, the roots of the facial nerve pass laterally and forward in the cerebellopontine angle, along with the vestibulocochlear and labyrinthine artery. All these structures then enter the internal acoustic meatus. In the meatus, the motor root is lodged in a groove on the vestibulocochlear nerve, whereas the sensory root remains separate. At the lateral end (bottom) of the internal acoustic meatus, two roots unite to form the trunk of the facial nerve. (Here, it is important to note that the bottom or fundus of the internal acoustic meatus forms the medial wall of the bony labyrinth of the internal ear.) The facial nerve enters the facial canal in the petrous temporal bone through its opening in the fundus of the internal acoustic meatus.

The facial canals divide into three segments: labyrinthine, tympanic, and mastoid.

The **labyrinthine segment** of the facial canal lies above the vestibule of bony labyrinth and bends to reach the anterosuperior part of the medial wall of the middle ear (tympanum) near the processus cochleariformis. Here, the canal bends sharply backward. The facial nerve coursing through the labyrinthine segment of canal also makes a sharp bend called the **external genu of the facial nerve** that possesses the geniculate ganglion.

The **tympanic segment** of the facial canal runs horizontally backward in the medial wall of the middle ear till it reaches the junction of the medial and posterior wall of the middle ear. The bulge of the tympanic segment of the facial canal is seen in the medial wall of the middle ear above the promontory and fenestra vestibuli and below the bulge produced by the lateral semicircular canal.

The **mastoid segment** begins at the junction of the medial and posterior wall of the middle ear, and passes vertically downward in the posterior wall of the middle ear till it reaches the stylomastoid foramen at the base of the skull.

The facial nerve comes out of cranial cavity through the stylomastoid foramen.

The extracranial course of the facial nerve is described in detail on page 116, [Chapter 8](#) ; also see page 57, [Chapter 3](#) .

### **Branches and distribution (Fig. 22.11 )**

1. **Greater petrosal nerve** arises from the geniculate ganglion. It consists of preganglionic parasympathetic fibres, which relay in the

pterygopalatine ganglion and supply the secretomotor fibres to the lacrimal gland and the mucous glands of nasal cavity and palate.

2. **Nerve to stapedius** arises from the vertical part of the facial nerve opposite the pyramidal eminence, runs forward through a short canal within it to reach the stapedius muscle to supply it.
3. **Chorda tympani nerve** arises from the vertical part of the facial nerve approximately 6 mm above the stylomastoid foramen, and enters the middle ear through the *posterior canaliculus* (on the posterior wall of the middle ear), runs across the lateral wall of the middle ear (pars flaccida of the tympanic membrane); passing between the long process of incus and the handle of malleus, and leaves the middle ear by entering the *anterior canaliculus* (on the anterior wall of the middle ear). It then traverses through the bony canaliculus and enters the infratemporal fossa through the medial end of *petrotympanic fissure*. After emerging from the petrotympanic fissure, it runs medially forward and downward, crossing the medial aspect of the spine of sphenoid, to join the posterior aspect of the lingual nerve.
  - The chorda tympani nerve consists of two types of fibres:
    - (a) *Preganglionic parasympathetic (GVE) fibres*, which provide secretomotor supply to the submandibular and sublingual glands.
    - (b) *SVA fibres*, which carry taste sensations from anterior two-third of the tongue.
4. **Posterior auricular nerve** supplies the occipital belly of occipitofrontalis.
5. Nerve to the posterior belly of digastric supplies the concerned muscle.
6. **Nerve to stylohyoid** supplies the concerned muscle.
7. **Five terminal branches** (temporal, zygomatic, buccal, marginal mandibular, and cervical) supply the muscles of facial expression.

## CLINICAL CORRELATION

- **Lesions of facial nerve:** These can be supranuclear or infranuclear (Figs 22.11 and 22.12).

✧ A **supranuclear lesion** (i.e., in hemiplegia) spares the upper part of the face because nuclear fibres supplying the muscles of the upper part of the face are innervated by the corticonuclear fibres of both

the cerebral hemispheres. In the supranuclear lesion, only lower half of the face on the opposite side is paralysed.

☞ All **infranuclear lesions** involve whole of the face on the same side.

☞ **The signs and symptoms of infranuclear lesions differ according to the site of the lesion ( Fig 22.11 ):**

#### **Site A**

■ *At or just above the stylomastoid foramen:* It causes *Bell's palsy* , which presents as loss of motor functions of all muscles of facial expression leading to the deviation of mouth towards the normal side, inability to close the mouth and eye, and accumulation of food in the vestibule of mouth flattening of expression lines (for details, see page 59).

#### **Site B**

■ *Above the origin of chorda tympani:* All the signs and symptoms of lesion A (i.e., Bell's palsy) plus decreased salivation and loss of taste sensations in the anterior two-third of the tongue.

#### **Site C**

■ *Above the origin of nerve to stapedius:* All the signs and symptoms of lesion B plus *hyperacusis* (i.e., enhanced sensitivity to hearing).

#### **Site D**

■ *At the geniculate ganglion:* All the signs and symptoms of lesion C plus loss of lacrimation.

- **Crocodile tear syndrome:** It is a clinical condition characterized by paroxysmal lacrimation during eating. It results in the facial nerve lesion proximal to the geniculate ganglion because regenerating preganglionic fibres meant to provide secretomotor supply to the submandibular and sublingual salivary glands during regeneration are misdirected and grow in the endoneural sheaths of preganglionic secretomotor fibres that supply the lacrimal gland.
- **Ramsay Hunt syndrome:** It occurs because of the involvement of geniculate ganglion in herpes zoster infection. *Clinically, it presents with the following signs and symptoms :*
  - ☞ Herpetic vesicles on the auricle
  - ☞ Hyperacusis
  - ☞ Loss of lacrimation
  - ☞ Loss of taste sensations in the anterior two-third of the tongue

• Complete ipsilateral facial palsy (Bell's palsy)

**FIG. 22.12 ■** Effects of supranuclear (UMN) and infranuclear (LMN) lesions of the facial nerve.

## Vestibulocochlear nerve

Vestibulocochlear nerve is the 8th cranial nerve. It consists of two distinct parts: (a) a vestibular part, called the **vestibular nerve**, and (b) a cochlear part, called the **cochlear nerve** (Fig. 22.13). The vestibular nerve is concerned with the maintenance of **equilibrium**, whereas the cochlear nerve is concerned with **hearing**.

**FIG. 22.13** ■ Schematic diagram showing the course and distribution of the vestibular and cochlear nerves. (A) Vestibular nerve; (B) cochlear nerve.

### Functional components and nuclei

**SSA fibres:** They carry sensory information necessary for the maintenance of equilibrium and hearing from the membranous labyrinth of the internal ear.

The fibres carrying the sensory information for equilibrium terminate in the vestibular nuclei within the brainstem.

The fibres carrying the sensory information for hearing terminate in the dorsal and ventral cochlear nuclei, located on the dorsal and ventral aspects of the inferior cerebellar peduncle, respectively.

### Course, relations and distribution

The **vestibular nerve** arises from the lateral aspect of the pontomedullary junction, passes through the pontocerebellar angle, and enters the internal acoustic meatus along with the facial nerve and labyrinthine vessels.

The **vestibular ganglion** (also called **Scarpa's ganglion**) is located on the vestibular nerve in the lateral part of the internal acoustic meatus. It consists of bipolar sensory neurons. In the lateral part of the internal acoustic meatus, the nerve divides into three distinct branches: superior and inferior divisions and singular nerve. These branches pass through the foramina in the fundus of the meatus and innervate the sensory receptors for equilibrium (cristae ampullaris and maculae) in the membranous labyrinth of the internal ear.

The **cochlear nerve** also arises from the lateral aspect of the pontomedullary junction and takes a similar course to enter the internal acoustic meatus. At the medial end of the internal acoustic meatus, it enters into bony labyrinth of the middle ear through **tractus spiralis foraminosus** in the fundus of the meatus and reaches the modiolus of the internal ear. In the modiolus, the cochlear nerve possesses a sensory ganglion called the *spiral ganglion* made of bipolar neurons. The peripheral process of these neurons innervates the sensory receptor of hearing – the *organ of Corti*.

## CLINICAL CORRELATION

- **Lesions of vestibulocochlear nerve:** The lesions of the vestibulocochlear nerve clinically present as:
  - ❧ (a) *Tinnitus* (ringing or buzzing in the ears)
  - ❧ (b) Impairment or loss of hearing
  - ❧ (c) Loss of balance (*vertigo*)

The vestibular nerve is commonly involved by *acoustic neuroma*, which arises from the sheath cells of its constituent fibres in the region of cerebellopontine angle. The acoustic neuroma is one of the common intracranial tumours, and if large, it may involve the adjacent trigeminal, facial, and glossopharyngeal nerves and may compress cerebellum and medulla.

## Last four cranial nerves AN 35.7

The last four cranial nerves are the nerves of the neck and closely related to each other, hence described together. The last four cranial nerves leave the skull close together, the glossopharyngeal, vagus, and accessory through the jugular foramen, and the hypoglossal nerve through the hypoglossal canal

(Fig. 22.14 ).

**FIG. 22.14** ■ Relationship of the last four cranial nerves at the base of the skull.

At first, they lie between internal jugular vein and the internal carotid artery, where cranial root of the accessory nerve joins the vagus nerve and is distributed through it. Thereafter, the glossopharyngeal nerve passes forward across the internal carotid artery and then deep to the external carotid artery. The spinal accessory nerve passes backward across the internal jugular vein and the vagus nerve passes straight down in the deeper plane between the internal jugular vein and the internal carotid artery. The hypoglossal nerve is medial to others, curves around behind the vagus nerve, and then passes forward, superficial to the vagus nerve, internal carotid, and external carotid arteries.

The close relationship of the last four cranial nerves can be well appreciated by studying the features of the base of the skull around the jugular foramen.

The **jugular foramen** is located in front of the jugular process of the occipital bone. The jugular fossa is a bony depression between the jugular foramen and base of the skull.

## Glossopharyngeal nerve

Glossopharyngeal nerve is the 9th cranial nerve. It is a mixed nerve, that is composed of both the motor and sensory fibres, but predominantly it is sensory. It derives its name from the fact that it provides sensory innervation to the tongue and pharynx.

### Functional components and nuclei (Fig. 22.15 )

1. **SVE fibres:** They supply the stylopharyngeus muscle. They arise from *nucleus ambiguus* .
2. **GVE fibres:** They supply the secretomotor fibres to the parotid gland. They are preganglionic parasympathetic fibres and arise from the *inferior salivatory nucleus*.
3. **SVA fibres:** They carry taste sensations from the posterior one-third of tongue including vallate papillae and terminate in the *nucleus tractus solitarius* . Their cell bodies are located in inferior ganglion of IX nerve.
4. **GVA fibres:** They carry general sensations of pain, touch, and temperature from the mucous membrane of the pharynx, tonsil, soft palate, and the posterior one-third of tongue and terminate in the lower part of N. tractus solitarius. Their cell bodies are located in inferior ganglion of IX N.
5. **GSA fibres:** They carry proprioceptive sensations from the stylopharyngeus and skin of the auricle and terminate in the *nucleus of the spinal tract of 5th nerve* . Their cell bodies are located in superior ganglion of IX N.

**FIG. 22.15 ■** Functional components and nuclei of the glossopharyngeal nerve.

### **Course and relations (Fig. 22.16 )**

The glossopharyngeal nerve arises from upper part of the lateral aspect of the medulla between olive and inferior cerebellar peduncle by three or four rootlets. The rootlets unite to form a single trunk which runs forward and laterally to leave the cranial cavity by passing through the intermediate compartment of the jugular foramen enclosed in a separate sheath of dura mater.

**FIG. 22.16 ■** Course and distribution of the glossopharyngeal nerve.

The **superior** and **inferior sensory ganglia** are located on the nerve as it passes through the jugular foramen.

The **smaller superior ganglion** lies within the jugular foramen and is considered the detached part of the inferior ganglion.

The **larger inferior ganglion** lies just below the jugular foramen and contains cell bodies of most of the sensory fibres of the nerve.

After emerging from the jugular foramen at the base of the skull, the nerve passes downward and forward between the internal carotid artery and the

internal jugular vein. It then descends anterior to the internal carotid artery to the styloid process and muscles attached to it (in this position, it lies lateral to the tonsillar bed formed by the superior constrictor) to reach the lower border of the stylopharyngeus. From here, it passes along with the stylopharyngeus through the gap between the superior and middle constrictors of the pharynx.

It then curves forward along the lateral aspect of the stylopharyngeus muscle which it supplies, and then passes deep to the stylohyoid ligament and posterior edge of the hyoglossus muscle. Here, it breaks up into terminal branches, which supply the mucous membrane of the posterior one-third of the tongue, pharynx, and tonsil.

### **Branches and distribution**

The glossopharyngeal nerve gives following important branches:

- 1. Tympanic branch (Jacobson's nerve):** It leaves the inferior ganglion and enters the middle ear through the tympanic canaliculus situated at the bony edge between jugular foramen and carotid canal. It forms the tympanic plexus over the promontory of the middle ear. The tympanic plexus gives off:
  - (a) The lesser petrosal nerve
  - (b) Twigs to tympanic cavity, auditory tube, and mastoid air cells.The lesser petrosal nerve carries the preganglionic parasympathetic fibres which relay in the otic ganglion. The postganglionic fibres from the ganglion supply the parotid gland.
- 2. Carotid nerve (nerve of Herring):** It is a branch to carotid sinus and carotid body. It serves as an afferent limb for pressoreceptor and chemoreceptor reflexes from the carotid sinus and carotid body to regulate the heart rate and respiration, respectively.
- 3. Pharyngeal branch:** It joins the pharyngeal branches of the vagus and the cervical sympathetic chain to form the *pharyngeal plexus* on the middle constrictor of the pharynx.
- 4. Branch to stylopharyngeus:** It arises as the nerve, winds around the stylopharyngeus muscle. *It is the only motor branch of the glossopharyngeal nerve.*
- 5. Tonsillar branches:** They supply the mucous membrane of tonsil, fauces, and palate.
- 6. Lingual branches:** They supply the posterior one-third of the tongue

and vallate papillae and convey taste and general sensations.

## CLINICAL CORRELATION

- **Lesions of glossopharyngeal nerve:** The lesion of the glossopharyngeal nerve is rare in isolation as there is often associated involvement of the vagus nerve. However, complete lesion of the glossopharyngeal nerve results in:
  - ❧ (a) The loss of taste and general sensations over the posterior one-third of the tongue
  - ❧ (b) Difficulty in swallowing
  - ❧ (c) The loss of the salivation from the parotid gland
  - ❧ (d) The unilateral loss of the gag reflex (see Chapter 14).
- **Glossopharyngeal neuralgia**, although rare, may occur. It is characterized by paroxysmal attacks of intractable pain in the area of the sensory distribution of the glossopharyngeal nerve, for example, throat, tongue, and ear, precipitated by swallowing.
- **Clinical testing of glossopharyngeal nerve:** The glossopharyngeal nerve can be tested clinically by:
  - ❧ (a) *Eliciting the gag reflex* (i.e., on tickling the posterior wall of the pharynx, soft palate, or tonsillar fossa, there is reflex contraction of pharyngeal muscles causing gagging and retching)
  - ❧ (b) Testing the taste sensations in the posterior one-third of the tongue.

## Vagus nerve

Vagus nerve is the 10th cranial nerve. It is a mixed nerve, i.e., composed of both motor and sensory fibres but predominantly it is motor. It is the longest and most widely distributed cranial nerve. It is so called because of its extensive course and distribution. It is a vagrant or wandering nerve. Its field of distribution extends beyond the head and neck, to the thorax and abdomen. It conveys most of the efferent fibres of the cranial part of the parasympathetic outflow and distributes the fibres of a cranial part to the accessory nerve.

## Functional components and nuclei (Fig. 22.17)

1. **SVE fibres** supply the muscles of palate, pharynx, and larynx. They

arise from *nucleus ambiguus* .

2. **GVE fibres** arise from the *dorsal nucleus of vagus* , and provide parasympathetic innervation to heart, bronchial tree, and most of the GIT.
3. **SVA fibres** carry taste sensations from the posterior-most part of the tongue and epiglottis and terminate in the *nucleus tractus solitarius* . Their cell bodies are located in inferior ganglion of X N.
4. **GVA fibres** carry general sensations from the mucous membrane of pharynx, larynx, trachea, oesophagus, and thoracic and abdominal viscera. terminate in the nucleus tractus solitarius. Their cell bodies are located in the inferior ganglion of X N.
5. **GSA fibres** carry general sensations from skin of the auricle and terminate in the *nucleus of the spinal tract of the trigeminal nerve* . Their cell bodies are located in superior ganglion of X N.

**FIG. 22.17 ■** Functional components and nuclei of the vagus nerve.

**Course and relations (Fig. 22.18 )**

The vagus nerve arises from the lateral aspect of the medulla between the olive and inferior cerebellar peduncle by approximately 10 rootlets below and in line of the rootlets of the glossopharyngeal nerve. These nerve rootlets unite to form the nerve trunk which runs laterally, crosses the jugular tubercle, and leaves the cranial cavity by passing through the middle part of the jugular foramen enclosed in the common dural sheath with the 11th cranial nerve.

**FIG. 22.18 ■** Course and distribution of the vagus nerve (right) in the head and neck.

The superior and inferior sensory ganglia are located on the nerve as it passes through the jugular foramen:

1. A smaller **superior ganglion** lies within the jugular foramen.
2. The **larger inferior (nodose) ganglion** lies just below the jugular foramen. Both the ganglia contain cell bodies of the sensory fibres of the vagus nerve. The *superior ganglion* contains the cell bodies of GSA fibres, whereas the inferior ganglion contains the cell bodies of visceral afferent fibres. The cranial root of the accessory (11th) nerve unites with the vagus nerve just below its inferior ganglion and thus transfers all its fibres to the vagus nerve for distribution.

After coming out of the cranial cavity through the jugular foramen, the nerve runs vertically downward within the carotid sheath in the neck first between the internal jugular vein laterally and the internal carotid artery medially and then between the internal jugular vein (laterally) and the common carotid artery (medially).

At root of the neck, the nerve enters the thorax. The **right vagus nerve** enters the thorax by crossing in front of the right subclavian artery, whereas the **left vagus nerve** enters the thorax by passing between the left common carotid and left subclavian arteries.

For course of vagus nerves in the thorax, see *Textbook of Anatomy: Upper Limb and Thorax*, Vol. I, 4ed. by Vishram Singh.

### **Branches and distribution (Fig. 22.18 )**

The branches and distribution of the vagus nerve in the region of head and neck are as follows:

1. **Meningeal branch:** It arises from the *superior ganglion*, takes a recurrent course, and enters the cranial cavity through the jugular foramen to supply the dura mater of the posterior cranial fossa.
2. **Auricular branch (Arnold's nerve or Alderman's nerve):** It arises from the *superior ganglion*, enters the *mastoid canaliculus* on

the lateral wall of the jugular fossa, and emerges through the tympanomastoid fissure just behind the external auditory meatus to supply the skin on the back of the meatus and adjoining part of the auricle. Then it enters the meatus between its bony and cartilaginous parts to supply the floor of the meatus and the tympanic membrane. Stimulation of this nerve, as in syringing of the ear, may cause reflex coughing (**ear cough**), vomiting, and even cardiac arrest.

3. **Pharyngeal branch:** It arises from the *inferior ganglion*, passes forward between the internal and external carotid arteries, and takes part in the formation of pharyngeal plexus. It supplies:
  - (a) All the muscles of pharynx *except* the stylopharyngeus, which is supplied by the glossopharyngeal nerve
  - (b) All the muscles of soft palate *except* the tensor palati, which is supplied by the mandibular nerve (through the nerve to medial pterygoid).
4. **Branches to carotid body:** It arises from the inferior ganglion.
5. **Superior laryngeal nerve (nerve of 4th arch):** It arises from the *inferior ganglion*, passes downward and forward deep to the internal carotid artery to reach the middle constrictor where it divides into external and internal laryngeal nerves:
  - (a) The *external laryngeal nerve (motor)* runs downward in company with superior thyroid vessels and supplies cricothyroid muscle. It also gives twigs to the inferior constrictor and pharyngeal plexus.
  - (b) The *internal laryngeal nerve (sensory)* passes downward and forward towards the gap between the middle and inferior constrictors. It pierces the thyrohyoid membrane to enter the larynx. It supplies:
    - (i) The mucous membrane of larynx above the vocal cords
    - (ii) The mucous membrane of the pharynx, epiglottis, vallecula, and the posterior-most part of the tongue.
6. **Superior and inferior cervical cardiac branches:** The *superior cardiac branch* arises in upper part of the neck and the *inferior cardiac branch* in lower part of the neck. They enter the thorax through the thoracic inlet. They carry preganglionic parasympathetic fibres to the heart and are cardioinhibitory. The *inferior cervical cardiac branch* of the left vagus nerve joins the *superficial cardiac plexus*. The remaining cervical cardiac branches of both the vagus

nerves join the *deep cardiac plexus* .

7. Recurrent laryngeal nerve (nerve of 6th arch):

- (a) *On the right side* , it arises in the root of the neck from the vagus nerve as it crosses in front of the subclavian artery, winds around the first part of the subclavian artery, and then ascends up (in a recurrent direction) in the tracheoesophageal groove.
- (b) *On the left side*, it arises in the superior mediastinum from the vagus nerve as it crosses the arch of the aorta (lateral aspect). It hooks below the arch of the aorta on the left side of *ligamentum arteriosum* behind the arch of aorta on its way to the tracheoesophageal groove.

The recurrent laryngeal nerve provides motor innervation to all the intrinsic muscles of the larynx (*except* the cricothyroid which is supplied by the external laryngeal nerve) and sensory innervation to the mucous membrane of laryngeal cavity up to the vocal cord.

Each recurrent laryngeal nerve passes deep to the inferior constrictor muscle to enter the laryngeal cavity deep to the cricothyroid joint. Now it is called the *inferior laryngeal nerve* .

## CLINICAL CORRELATION

- **Alderman's nerve phenomenon:** The tickling of the cutaneous distribution of the vagus nerve stimulates jaded appetite. The Alderman in ancient Roman days used to stimulate their appetite by dropping cold water behind the ear supplied by the *auricular branch of the vagus nerve* . For this reason, the auricular branch of the vagus nerve is also called *Alderman's nerve* . Apparently, this occurs by a reflex increase in gastric motility supplied by the vagus nerve (to the stomach).
- **Lesions of vagus nerve:** The bilateral lesions of vagus nerve cause:
  - ❧ (a) Nasal regurgitation of the swallowed liquids
  - ❧ (b) Nasal twang of voice
  - ❧ (c) Hoarseness of voice
  - ❧ (d) Flattening of palatal arches
  - ❧ (e) Cadaveric position of vocal cords
  - ❧ (f) Dysphagia
  - ❧ (g) Loss of cough reflex.
- **Clinical testing of vagus nerve:** The vagus nerve can be tested

clinically by asking the patient to open his or her mouth and say 'ah', and then comparing the palatal arches of the two sides. If the vagus is intact, the soft palate rises (is elevated) in the midline. In bilateral lesions, the soft palate drops. In unilateral lesion, there is flattening (drooping) of palate arch on the side of paralysis and uvula pulled to the normal side.

## Accessory nerve

Accessory nerve is the 11th cranial nerve. It is purely motor. It consists of two roots: cranial and spinal.

The **cranial root** is accessory to the vagus and its fibres are distributed through the vagus nerve.

The **spinal root** has an independent course and is generally regarded as **spinal accessory nerve**, or simply as **accessory nerve**.

## Functional components and nuclei (Fig. 22.19 )

1. **SVE fibres** provide motor supply to the muscles of soft palate, pharynx, and larynx. They arise from the *nucleus ambiguus* and form the cranial root.
2. **GSE fibres** provide motor supply to the sternocleidomastoid and trapezius muscles. They arise from the *spinal nucleus of accessory nerve*, in the ventral horns of the upper five spinal segments and form the spinal root.

**FIG. 22.19** ■ Functional components and nuclei of the accessory nerve.

### Course and relations (Fig. 22.20 )

The **cranial root** arises by four or five rootlets from the posterolateral sulcus of the medulla between the olive and inferior cerebellar peduncle. The rootlets are attached in line with the rootlets of the vagus nerve above. These rootlets unite together to form a single trunk which runs laterally along with the 9th and 10th cranial nerves to reach the jugular foramen where it is joined by the spinal root.

**FIG. 22.20 ■** Distribution of the cranial and spinal roots of the accessory nerve.

The **spinal root** arises by a number of rootlets from the lateral aspect of the spinal cord (upper five cervical spinal segments) along a vertical line between the ventral and dorsal roots of the spinal nerves. These rootlets unite to form a single trunk which ascends in the vertebral canal to enter cranial cavity through the foramen magnum behind the vertebral artery. The spinal root leaves the skull through the jugular foramen where it fuses with the

cranial root. The combined trunk comes out of the cranial cavity through the middle compartment of the jugular foramen enclosed in the dural sheath along with the vagus nerve. Immediately after coming out of the cranial cavity, the two roots again separate. The cranial root joins the vagus nerve just below its inferior ganglion and is distributed through the branches of the vagus to the muscles of the palate, pharynx, and larynx.

The spinal root of the accessory nerve descends vertically downward between internal jugular vein and the internal carotid artery. As it reaches a point midway between the angle of the mandible and the mastoid process, it turns downward and backward across (superficial or deep) the internal jugular vein towards the carotid triangle. It crosses in front of the transverse process of the atlas under the posterior belly of the digastric muscle and occipital artery. Here, it is accompanied by the upper sternomastoid branch of the occipital artery.

The nerve pierces the sternocleidomastoid muscle at the junction of its upper one-fourth with the lower three-fourth and supplies it. The nerve passes through the muscle and emerges through its posterior border a little above its middle to enter the posterior triangle where it runs downward and backward underneath the fascial roof of the posterior triangle, parallel to the fibres of levator scapulae.

It leaves the posterior triangle by passing deep to the anterior border of the trapezius approximately 5 cm above the clavicle.

The spinal accessory nerve communicates with the C2, C3, and C4 spinal nerves. The C2 and C3 spinal nerves carry proprioceptive fibres from the sternocleidomastoid, whereas C3 and C4 carry proprioceptive fibres from the trapezius muscle.

### **Distribution (Fig. 22.20 )**

The **cranial root** of the accessory nerve via the vagus nerve and pharyngeal plexus of nerves supplies:

1. All the muscles of the palate *except* the tensor palati which is supplied by the mandibular nerve (nerve to medial pterygoid):
  - (a) All muscles of the pharynx *except* the stylopharyngeus, which is supplied by the glossopharyngeal nerve.
  - (b) All intrinsic muscles of larynx.

The **spinal root** of the accessory nerve supplies the following two muscles:

1. Sternocleidomastoid muscle along with C2 and C3 spinal nerves
2. Trapezius muscle along with C3 and C4 spinal nerves.

## CLINICAL CORRELATION

- **Lesions of spinal accessory nerve:** It may be damaged by the fracture base of the skull through the jugular foramen or stab wounds in the neck or during the surgical removal of cervical lymph nodes.

***Unilateral lesion of the spinal accessory nerve proximal to sternocleidomastoid causes:***

- *Ipsilateral paralysis of the sternocleidomastoid* , with the result that the patient is unable to tilt his or her head towards the ipsilateral shoulder and unable to turn his or her face towards the opposite side
  - *Paralysis of trapezius* , with the result that the patient is unable to shrug his or her shoulder against the resistance.
- **Spasmodic torticollis:** It may result from irritative central lesions of the spinal accessory nerve. It is characterized by clonic spasms of the sternocleidomastoid muscle.
  - **Clinical testing of spinal accessory nerve:** The *sternocleidomastoid muscle* is tested by asking the patient to turn his or her face to the opposite side against the resistance offered by the examiner's hand. In a normal condition, a person can do it and sternocleidomastoid stands out prominently.

The *trapezius muscle* can be tested by asking the patient to shrug his or her shoulder against the resistance.

## Hypoglossal nerve

Hypoglossal nerve is the 12th cranial nerve. It is purely a motor nerve.

### Functional components and nuclei (Fig. 22.21 )

**GSE fibres:** These fibres arise from the hypoglossal nucleus and supply all the muscles of the tongue (extrinsic and intrinsic) that develop from occipital myotomes.

**FIG. 22.21 ■** Functional components and nucleus of the origin of the hypoglossal nerve.

### Course and relations

The hypoglossal nerve arises on the ventral aspect of the medulla from the anterolateral sulcus between the pyramid and the olive by 10–15 rootlets.

The rootlets of the hypoglossal nerve are attached in line with the rootlets of the ventral root of the 1st cervical spinal nerve.

The rootlets of the hypoglossal nerve run laterally and pass behind the vertebral artery to form two roots. The two roots pierce the dura mater separately near the anterior condylar or hypoglossal canal in which they enter. In the canal, the two roots unite to form a single trunk and come out of the cranial cavity.

After coming out of the cranial cavity, the nerve lies deep to the internal carotid artery and the 9th and 10th cranial nerves. It then passes downward and laterally behind the internal carotid artery and the 9th and 10th cranial nerves to reach the interval between the internal jugular vein and the internal carotid artery. Now it descends vertically in this interval in front of the 10th cranial nerve up to the level of the angle of the mandible. Here, the nerve curves forward crossing in front of the internal and external carotid arteries,

and the loop of the 1st part of the lingual artery to reach the posterior margin of the hyoglossus muscle by passing deep to the tendon of the posterior belly of the digastric. Now it runs on the superficial surface of the hyoglossus, muscle below the deep part of the submandibular gland. At the anterior margin of the hyoglossus, it lies on the genioglossus and runs forward and upward up to the tip of the tongue and ends by dividing into its terminal branches which supply the muscles of the tongue.

### **N.B.**

Some fibres of the 1st cervical nerve (ventral ramus) join the hypoglossal nerve and are distributed through its branches.

### **Branches and distribution (Fig. 22.22 )**

The hypoglossal nerve gives the following branches:

1. **Branches of the hypoglossal proper:** They supply all the muscles of the tongue *except* palatoglossus which is supplied by the cranial root of accessory nerve via the pharyngeal plexus.
2. Branches of the hypoglossal nerve containing C1 fibres: These are as follows:
  - (a) *Meningeal branch:* It arises from the nerve as it comes out through the hypoglossal canal taking a recurrent course, enters the cranial cavity through the hypoglossal canal, and supplies the dura mater of the posterior cranial fossa.
  - (b) *Descendens hypoglossi* or *upper root of ansa cervicalis:* It arises as the nerve crosses in front of the internal carotid artery. It runs downward to join the inferior root of ansa cervicalis at the level of cricoid cartilage.
  - (c) *Nerve to thyrohyoid:* It crosses the greater cornu of the hyoid bone to reach the muscle.
  - (d) *Nerve to geniohyoid:* It arises above the hyoid bone.

**FIG. 22.22 ■** Course and distribution of the hypoglossal nerve.

## CLINICAL CORRELATION

- **Infranuclear lesions of hypoglossal nerve AN 39.2 :** If the hypoglossal nerve is cut on one side during surgical operations, such as carotid endarterectomy, there will be *lower motor neuron type of paralysis* of muscles of the tongue on same side. On asking the patient to protrude his or her tongue, the tip of the tongue deviates to the paralysed side because of the unopposed action of the muscles of the healthy side. It may be associated with fasciculations.
- **Supranuclear lesions, such as cerebral stroke,** involve corticonuclear fibres (upper motor neuron type of paralysis). Clinically, the tongue deviates to the opposite side. There are slow spastic tongue movements. The supranuclear lesions commonly occur due to cerebral stroke, but can be caused by pseudobulbar palsy.
- **Clinical testing of hypoglossal nerve:** To test the integrity of the hypoglossal nerve, the functions of genioglossus muscles are assessed.

The patient is asked to protrude the tongue. If the hypoglossal nerves of both sides are intact, the protruded tongue lies in the midline.

◻ If the hypoglossal nerve of one side is damaged, the tongue deviates to the side of the lesion/paralysis.

◻ If the hypoglossal nerves of both sides are damaged, the patient cannot protrude his or her tongue. It lies motionless in mouth causing difficulty in speech and swallowing.

### **Golden Facts to Remember**

• <b>Most slender cranial nerve</b>	Trochlear nerve
• <b>All the cranial nerves arise from ventral aspect of the brain <i>except</i></b>	Trochlear nerve, which arises from dorsal aspect of the brain
• <b>Largest cranial nerve</b>	Trigeminal nerve
• <b>Longest cranial nerve</b>	Vagus nerve
• <b>Most frequently paralysed cranial nerve</b>	Facial nerve
• <b>Most commonly involved cranial nerve in increased intracranial pressure</b>	Abducent nerve
• <b>All the branches of glossopharyngeal nerve are sensory <i>except</i></b>	Nerve to the stylopharyngeus, which is motor
• <b>Most common condition affecting the sensory part of the trigeminal nerve</b>	Trigeminal neuralgia (tic douloureux)
• <b>All the sensory ganglia lie outside the cranial cavity <i>except</i></b>	Trigeminal ganglion, which lies within the cranial cavity
• <b>Only monosynaptic reflex present in the brain</b>	Masseteric reflex (or jaw jerk)
• <b>Cranial nerve having the longest bony course</b>	Facial nerve
• <b>All the cranial nerves are true peripheral nerves <i>except</i></b>	Optic nerve which is (truly speaking) a tract of brain
• <b>Cranial nerve with longest intracranial course</b>	Abducent nerve
• <b>Cranial nerves causing strabismus</b>	III, IV and VI

## CLINICAL CASE STUDY

A 70-year-old patient having long-standing high blood pressure suffered from a stroke. He was taken to the hospital where he was diagnosed as a case of hemiplegia. The hemiplegia was associated with the upper motor neuron type of facial palsy. On examination, the lower half of left half of the face was found to be paralysed. He was able to smile normally when he enjoyed a joke. He was diagnosed as a case of **UMN type of facial palsy**.

### Questions

1. Why in the upper motor neuron type of facial palsy the upper part of face is usually spared?
2. How could a patient with hemiplegia smile normally?
3. What is Bell's palsy?

### Answers

1. Because of the fact that it is innervated by both the cerebral hemispheres.
2. It is thought that such movements (e.g., smile) may have supranuclear connections separate from those commonly involved in hemiplegia, which probably do not descend in the internal capsule.
3. It is the lower motor neuron type of the facial palsy due to the compression of facial nerve at or just above the stylomastoid foramen.

# SECTION II: Brain

## OUTLINE

---

- 23. Overview of brain, meninges and cerebrospinal fluid
- 24. Brainstem and functional column of cranial nerve nuclei
- 25. Cerebellum and fourth ventricle
- 26. Diencephalon and third ventricle
- 27. Cerebrum
- 28. Basal nuclei and limbic system
- 29. Blood supply of the brain
- 30. Surface anatomy of head, neck and brain

---

# Chapter 23: Overview of brain, meninges and cerebrospinal fluid

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe various layers of meninges with their extent and modifications. **AN 56.1**
- Describe the circulation of CSF with its applied anatomy. **AN 56.2**
- Give the anatomical basis of congenital hydrocephalus. **AN 63.2**
- Write short notes on: (a) interpeduncular fossa, (b) ventricles of brain, (c) subarachnoid cisterns, and (d) brainstem.
- Enumerate: (a) lobes of cerebral hemisphere, (b) basal nuclei, (c) clinical features of hydrocephalus, and (d) cranial nerves.

The central nervous system (CNS) consists of the brain and the spinal cord. The brain lies within the cranial cavity and the spinal cord lies within the vertebral canal.

Structurally, both the brain and the spinal cord consist of grey and white matter. Therefore, sections through the CNS present greyish and whitish regions. The **grey matter** consists of nerve cell bodies and dendrites, and the **white matter** is made up predominantly of myelinated nerve fibres. In the brain (except the brainstem), the grey matter is present at the periphery and the white matter in the centre. Contrary to this in the spinal cord, the grey matter is present in the centre and the white matter at the periphery.

Functionally, the CNS is concerned with: (1) the **reception and integration of sensory information** from within and outside the body, and (2) the **production of motor responses** which are appropriate to the sum of the sensory information received by it.

The CNS develops from a hollow **neural tube** whose cavity persists in the adult brain and spinal cord in form of different cavities. The spinal cord is described in detail in [Chapter 20](#) , page 295.

Developmentally, the brain consists of the **forebrain**, **midbrain**, and **hindbrain** . The forebrain consists of the cerebrum and diencephalon. The midbrain is a small region which connects the forebrain with the hindbrain. The hindbrain consists of the pons, medulla oblongata, and cerebellum. The midbrain, pons, and medulla collectively form the **brainstem** .

The parts of brain and cavities within them are listed in [Table 23.1](#) .

---

 **TABLE 23.1**

---

### **Parts of the brain and their cavities**

---

<b>Part of brain</b>	<b>Cavity</b>
Cerebrum (right and left cerebral hemispheres)	Right and left lateral ventricles
Diencephalon (thalamus and hypothalamus)	3rd ventricle
Midbrain	Cerebral aqueduct
Hindbrain (pons, medulla, and cerebellum)	4th ventricle

## **Brain**

The brain is that part of the CNS which lies within the cranial cavity.

The adult brain constitutes approximately one-fiftieth of the body weight and weighs approximately 1400 g in males and 1200 g in females.

### **Parts of brain**

It consists of the following six major parts ([Fig. 23.1](#) ):

1. Cerebrum
2. Diencephalon
3. Midbrain
4. Pons
5. Medulla oblongata
6. Cerebellum.

**FIG. 23.1** ■ Parts of the central nervous system.

## Cerebrum

The cerebrum is the largest part of the brain. It consists of two large hemispheres (**left** and the **right cerebral hemispheres**), which occupy anterior and middle cranial fossae, and the supratentorial region of the posterior cranial fossa.

Each cerebral hemisphere consists of a surface layer of grey matter, called the **cerebral cortex**, and a **central core** of white matter. In the basal part of the latter, large masses of grey matter, known as **basal nuclei/ganglia**, are located.

The two hemispheres are partly separated from each other by a deep median longitudinal fissure, called the **longitudinal cerebral fissure**. A massive commissure, the **corpus callosum**, whose fibres interconnect the corresponding cortical areas of the two cerebral hemispheres, lies in the floor of this fissure.

The surface of cerebral cortex is convoluted, i.e., it has a series of

elevations, the **gyri**, separated by shallow depressions, the **sulci** or deep grooves called **fissures** (Fig. 23.2 ).

**FIG. 23.2** ■ Left lateral aspect of the brain. Note the four lobes on the superolateral surface of the cerebral hemisphere.

There are individual differences in the appearance of the sulci and gyri, but some sulci are constant in their position and appearance and serve as important landmarks.

## Surfaces

**The superolateral surface of each cerebral hemisphere** is divided into four lobes which are named after the overlying skull bones:

1. **Frontal lobe** is anterior to the central sulcus and above the lateral sulcus. It is mainly responsible for motor functions and higher level of executive functions and abstract thinking.
2. **Parietal lobe** is posterior to the central sulcus and above the lateral sulcus. It is mainly responsible for processing of somatosensory

information, i.e., stereognosis.

3. **Occipital lobe** is behind a line extending from the parieto-occipital sulcus to the preoccipital notch. It is mainly responsible for processing of visual sensations (vision).
4. **Temporal lobe** is below the lateral sulcus and in front of preoccipital notch. It is mainly responsible for processing of auditory sensations (hearing).

The functions of various lobes are summarized below:

### Frontal lobe

Motor functions, motivation, aggression, emotions, affect, drive, and awareness of self.

### Parietal lobe

Reception and evaluation of all sensory information except smell, hearing, and vision.

### Occipital lobe

Reception and integration of visual input.

### Temporal lobe

Reception and integration of smell and hearing and plays an important role in memory.

### N.B.

Deep within the lateral sulcus lies a submerged portion of cerebral cortex, the **insula** which is often referred to as the *5th lobe* or the *central lobe* of the cerebral hemisphere.

The so called **limbic lobe** is a composite bordering zone (limbus = border) between the cerebrum and diencephalon. It is somewhat ring shaped. *It is associated with basic survival instincts*, namely, the acquisition of food and water and reproduction. It provides ability to store and retrieve information and is particularly important for short-term memory.

The **medial surface of the cerebral hemisphere** is visualized in the sagittal section of the brain and presents a number of features shown in [Figure 23.3](#).

**FIG. 23.3 ■** Median sagittal section of the brain.

The **inferior surface of the cerebral hemisphere** is uneven and presents orbital and tentorial surfaces.

### **Basal nuclei/basal ganglia**

The basal ganglia are subcortical masses of grey matter situated deep in the white core of each cerebral hemisphere. The basal ganglia include **corpus striatum, claustrum, and amygdaloid body** .

During the development of connections between the cerebral cortex and the brainstem, the bundles of fibres converging as **internal capsule** partly divide the corpus striatum into a medial **caudate nucleus** and a lateral **lentiform nucleus** . Between the internal capsule and the cerebral cortex, the nerve fibres diverge as the **corona radiata** .

Functionally, the basal ganglia also include the **subthalamic nucleus** of diencephalon, and the **substantia nigra** and **red nucleus** of midbrain.

The basal ganglia are termed as **extrapyramidal nuclei** .

### **Functions**

The basal nuclei are responsible for execution of fine motor functions, i.e., timing of movements, scaling of velocity of movements, automatic associated movements, and muscle tone. The lesions of basal nuclei lead to Parkinson

disease (see [Fig. 28.4](#) , page 390).

## Diencephalon

The diencephalon is the part of brain between the cerebrum and the brainstem. It is almost entirely hidden from surface view by the cerebral hemispheres. The main components of the diencephalon are as follows:

1. Thalamus
2. Hypothalamus
3. Metathalamus
4. Epithalamus
5. Subthalamus.

## Thalamus

The thalamus is a large ovoid mass of grey matter lying above the midbrain. The two thalami form by far the largest mass of the diencephalon and are separated from each other by a cavity of 3rd ventricle, and joined with each other by an **interthalamic adhesion** .

It forms a **great relay station for all sensory impulses** *except* olfactory, visual, and auditory. It also appreciates crude sensations such as pain and touch.

## Hypothalamus

The hypothalamus lies below the thalamus and connected to the pituitary gland by hypothalamohypophyseal tract and hypothalamohypophyseal portal system. It contains several small nuclei and nerve tracts. The most conspicuous nuclei called **mammillary bodies** appear as rounded elevations on the base of the brain in the region of interpeduncular fossa.

*The hypothalamus regulates visceral activity through the autonomic nervous system and hormonal activity through the hypophysis cerebri . It also acts as a biological clock .*

## Metathalamus

The metathalamus consists of two rounded medial and lateral geniculate bodies which protrude from the posteroinferior surface of the thalamus.

The medial and lateral geniculate bodies form relay stations for the special senses of hearing and vision, respectively.

## Epithalamus

The epithalamus is a small area of diencephalon, posterosuperior to the thalamus. It consists of pineal gland and habenular nuclei. The *pineal gland plays an important role in controlling the onset of puberty through its secretion – the melatonin* . The reduction of pineal secretion precipitates puberty. The pineal gland is also involved in *sleep –wake cycle* .

The habenular nuclei have olfactory and limbic connections. They are influenced by smell and are involved in emotional and visceral responses to odours.

## Subthalamus

The subthalamus is a small area of diencephalon that lies between the thalamus and the midbrain. It contains several nerve tracts and the subthalamic nuclei which are associated with basal ganglia and are involved in controlling motor functions.

## Midbrain

The midbrain is the smallest segment of the brainstem. It is just superior to the pons and contains the nuclei of the 3rd (oculomotor), 4th (trochlear), and 5th (trigeminal) cranial nerves.

The midbrain is traversed by the **cerebral aqueduct** . The part dorsal to the aqueduct is called the **tectum** and consists of four surface elevations – the **corpora quadrigemina** comprising *two superior and two inferior colliculi* .

*The superior and inferior colliculi receive visual and auditory impulses, respectively, and are concerned with reflexes involving these senses .*

The part ventral to the aqueduct is divided into right and left halves, the **cerebral peduncles** . Each cerebral peduncle consists of a central part, the tegmentum, which is separated ventrally from the crus cerebri by a mass of pigmented grey matter, the substantia nigra.

The crus cerebri continues ipsilaterally with the internal capsule above and contains descending fibres from the cerebral cortex to the brainstem and spinal cord. The space between the two crura is termed the **interpeduncular fossa** .

The tegmentum largely consists of ascending tracts from the spinal cord to the thalamus and contains two large cigar-shaped nuclei called **red nuclei** . In cross-section, the red nuclei appear as oval masses of the pinkish grey matter.

*The red nuclei help in unconscious regulation and coordination of motor activities.*

## **Pons**

The pons (Latin, *Pons* = bridge) is the large middle part of the brainstem. It is continuous above with the midbrain and below with the medulla oblongata. It is so named because it forms a broad bridge between the two cerebellar hemispheres by its transverse fibres constituting the middle cerebellar peduncles. The vertical median sulcus on its ventral aspect lodges the basilar artery, and therefore, termed the *basilar sulcus*.

In the transverse section, the pons is seen to consist of a large ventral and a smaller dorsal region.

The **ventral portion** contains a large number of nuclei, the **pontine nuclei** and longitudinal bundles of descending fibres of the pyramidal tract. The pontine nuclei relay information from the cerebrum to cerebellum and form a **corticopontocerebellar pathway**.

The **dorsal portion** or tegmentum of pons contains **pontine sleep and respiratory centres**. The pontine respiratory centre functions with the respiratory centre in the medulla to help in controlling the respiratory movements.

## **Medulla oblongata**

The medulla oblongata is the lower part of the brainstem and is continuous inferiorly with the spinal cord at the foramen magnum.

On the ventral aspect of medulla, there are two pyramid-shaped elevations, one on either side of median plane called **pyramids**. These elevations are produced by the descending fibres of the corticospinal tracts involved in the conscious control of the skeletal muscles. Lateral to the pyramids, there are two oval elevations called **olives** containing inferior olivary nuclei. Dorsal to each olive is an *inferior cerebellar peduncle*.

On the dorsal aspect, on either side, the medulla has cuneate and gracile tubercles produced by similarly named nuclei beneath them.

*Medulla contains various vital autonomic centres responsible for several reflexes such as those involved in the regulation of heart rate, blood vessel diameter, breathing, swallowing, vomiting, coughing, and sneezing.*

## **Cerebellum**

The cerebellum lies dorsal to the pons and medulla and consists of **two**

**lateral hemispheres** : the cerebellar hemispheres and a median worm-like part called **vermis** . It is connected to the midbrain, pons, and medulla by superior, middle, and inferior cerebellar peduncles, respectively. The surface of cerebellum has narrow transverse ridges called **folia** (leaf-like in sections) separated by deep fissures.

*Functionally, the cerebellum is mainly concerned with the involuntary control of somatic motor activities, essential for the maintenance of equilibrium, muscle tone, and posture.*

## Base of the brain

The base of the brain presents: (1) orbital and tentorial surfaces of the frontal and temporal lobes of the cerebral hemispheres; (2) interpeduncular fossa; (3) ventral aspects of the midbrain, pons, medulla oblongata, and cerebellum; and (4) superficial attachments of the cranial nerves ([Fig. 23.4](#) ).

**FIG. 23.4** ■ Interior aspect of the brain. Note the attachment of cranial nerves.

The interpeduncular fossa and superficial attachment of cranial nerves are

briefly described here.

### Interpeduncular fossa (Fig. 23.5 )

The interpeduncular fossa is a rhomboidal space bounded on either side by the crus cerebri of cerebral peduncles, anteriorly by optic chiasma and optic tracts, and posteriorly by the pons. The interpeduncular fossa contains: (1) two small spherical bodies called **mammillary bodies** ; (2) a raised area of grey matter lying anterior to the mammillary bodies called **tuber cinereum** ; (3) a narrow stalk which connects the hypophysis cerebri with the tuber cinereum called **infundibulum** ; (4) **posterior perforated substance** , which is a layer of grey matter in the angle between the crus cerebri and is pierced by the central branches of the posterior cerebral arteries; and (5) the **oculomotor** nerve which emerges immediately dorsomedial to the corresponding crus.

**FIG. 23.5** ■ Boundaries and contents of the interpeduncular fossa.

## **Superficial attachments of the cranial nerves**

All the 12 pairs of cranial nerves are attached on the ventral aspect of the brain *except* the 4th pair (trochlear nerves) which are attached on the dorsal aspect.

Each cranial nerve enters or leaves the brain surface at its superficial attachment, and the fibres which it contains arise either from (efferent or motor fibres) or terminate in (afferent or sensory fibres) motor and sensory nuclei within the brain, respectively.

The first two pairs are attached to the forebrain; the 3rd and 4th to the midbrain; and the remainder to the hindbrain. The 11th cranial nerve also receives a root from the upper part of the spinal cord.

## **Sites of attachments**

### **Olfactory nerves**

There are approximately 20 olfactory nerves on each side. They arise from the olfactory epithelium of nasal cavity and pass through the cribriform plate of ethmoid, and end in the olfactory bulb which lies on the orbital surface of the frontal lobe. They are so delicate that no trace is seen on the olfactory bulb when the brain is removed from the cranial cavity.

### **Optic nerve**

This is a thick cylindrical nerve which arises from the retina and joins the anterolateral angle of the optic chiasma.

### **Oculomotor nerve**

It emerges from the groove on the medial aspect of the cerebral peduncle in the posterior part of the interpeduncular fossa.

### **Trochlear nerve**

It is a slender nerve which emerges on the dorsal aspect of the midbrain, lateral to the median plane. It winds around the lateral aspect of the midbrain towards the interpeduncular fossa, immediately superior to the pons.

### **Trigeminal nerve**

It is the largest of the cranial nerves and attached to the junction of the pons and middle cerebellar peduncle by two roots: a large lateral sensory root and a small medial motor root.

### **Abducent nerve**

It emerges at the inferior border of the pons, opposite to the upper end of the medullary pyramid.

### **Facial nerve**

It emerges at the inferior border of pons lateral to the abducent nerve by two roots: a thick medial motor root and a slender lateral sensory root called *nervus intermedius*.

### **Vestibulocochlear nerve**

It consists of two nerves: vestibular and cochlear which are attached in the *cerebellopontine angle* .

### **Glossopharyngeal nerve**

It emerges by a number of rootlets from a groove between the olive and inferior cerebellar peduncle.

### **Vagus nerve**

It also emerges by a number of rootlets from a groove between the olive and inferior cerebellar peduncle below the rootlets of the glossopharyngeal nerve.

### **Accessory nerve**

It has two roots: cranial and spinal. The cranial root emerges by a number of rootlets from the medulla below the rootlets of the vagus nerve, and it is joined by the spinal root, which emerges by a number of rootlets from the upper five cervical spinal segments.

### **Hypoglossal nerve**

It arises by a row of rootlets from a groove between the pyramid and olive.

### **Ventricles of the brain**

There are four ventricles of the brain ([Fig. 23.6](#)): two lateral ventricles, a 3rd ventricle, and a 4th ventricle.

**FIG. 23.6 ■** Ventricles of the brain.

The two lateral ventricles, one in each cerebral hemisphere, form the largest component of the ventricular system. They occupy a considerable part of the cerebral hemisphere and are separated from each other by the septum pellucidum, extending between the corpus callosum and the fornix. The 3rd ventricle is a narrow slit-like cavity of the diencephalon. The two lateral ventricles are connected with the 3rd ventricle via the **interventricular foramina (of Monro)**. The 3rd ventricle communicates via the **cerebral aqueduct** of midbrain with the 4th ventricle, a cavity within the hindbrain. The 4th ventricle, in turn, is continuous with the central canal of the spinal cord. The central canal has a small dilatation at its inferior end, the **terminal ventricle**.

The cerebrospinal fluid (CSF) is formed in the ventricles by the choroid plexuses and passes through apertures in the roof of 4th ventricle into the subarachnoid space around the brain and spinal cord.

## **Membranes of the brain (meninges) AN 56.1**

The brain and spinal cord are enclosed within three protective membranes called meninges ([Fig. 23.7](#)). From without inward, these are as follows:

1. Dura mater
2. Arachnoid mater

### 3. Pia mater.

**FIG. 23.7 ■** Median section of the brain showing membranes, cisterns, and circulation of CSF.

The dura mater is mesodermal in origin, whereas the arachnoid mater and pia mater are ectodermal in origin (derived from neural crests).

#### **Dura mater**

The dura mater is tough outermost membrane, enveloping the brain and spinal cord. Accordingly, it is divided into cranial and spinal dura. The cranial dura has already been described in [Chapter 21](#) , page 312.

#### **Arachnoid mater**

The arachnoid mater is an exceedingly thin transparent membrane, which invests the brain loosely and continues as the spinal arachnoid at the foramen magnum, which ends at the level of 2nd sacral vertebra. It is closely related to the internal surface of the dura mater and has exactly the same shape as the dural sac except where its arachnoid granulations pierce the dura mater.

The arachnoid mater is separated from the dura mater by a capillary space called the **subdural space** containing a film of fluid. This forms a sliding plane where movement is possible between the dura mater and brain enclosed in the arachnoid and pia mater.

The subdural space is traversed by cerebral veins on their route to the dural venous sinuses.

## Processes of arachnoid mater

**Arachnoid villi:** These are fine finger-like processes which arise from the surface of arachnoid. They push the dura before them and eventually perforate it to project into the dural venous sinuses. They are covered by specialized mesothelial cells which convey the CSF to bloodstream, thus leading to the absorption of CSF.

**Arachnoid granulations (pacchionian bodies):** With advancing age, the arachnoid villi enlarge in size and form pedunculated tufts called **arachnoid granulations**. Some consider that these are aggregations of arachnoid villi, clumped together, i.e., arachnoid granulations are the large clustres of arachnoid villi. Arachnoid granulations like arachnoid villi are concerned with the absorption of CSF. They project into the venous lacunae of the superior sagittal sinus.

## Pia mater

Pia mater is a thin transparent vascular membrane which closely invests the surface of the brain. It is adherent to the surface of the brain and follows closely the irregularities of its surface.

All the blood vessels to the brain run in the subarachnoid space on the surface of the pia mater before entering the brain.

In certain situations, the walls of the cavities of the brain (ventricles) are very thin and made up of only a single layer of its lining epithelium, the **ependyma**. In these regions, the pia mater lying on its external surface invaginates into ventricular cavities as a series of vascular tufts of capillaries which carry the ependyma before them, thus forming the **choroid plexuses of the brain**. The pial component of choroid plexus is termed **tela choroidea**.

## Subarachnoid space

The subarachnoid space is the space between the arachnoid mater and pia mater. It is filled with CSF which enters it from the ventricular system of the brain.

The subarachnoid space is traversed by thread-like trabeculae passing from

the arachnoid to pia, giving it a **spider-web appearance**, hence the name arachnoid (arachnoid = like spider's web), and forms a kind of fluid-filled sponge. The arteries and veins of the brain lie in this space. Even the cranial nerves attached to the brain traverse this space.

The subarachnoid space around the brain is continuous with the subarachnoid space around the spinal cord at the foramen magnum and communicates with the ventricular system only through the foramina in the roof of the 4th ventricle.

The CSF in the subarachnoid space acts as a mobile buffer to distribute and equalize pressures within the skull.

### **Subarachnoid cisterns**

The enlargements of subarachnoid space, in certain situations, around the brain are termed **subarachnoid cisterns**. They contain large amount of CSF forming '**pools of CSF**'. The cisterns are found where the brain, closely covered with pia mater, lies at some distance from the arachnoid lining the dura mater. The cisterns act as a water-bed to the brain.

The various types of subarachnoid cisterns are as follows:

1. **Cerebellomedullary cistern (cisterna magna)** : It is the largest cistern and formed by the arachnoid, bridging the interval between the medulla oblongata and inferior surface of the cerebellum. Thus, it lies in the triangle formed by the cerebellum, the medulla oblongata, and the occipital bone. It is directly continuous inferiorly with the posterior part of the spinal subarachnoid space.
  - The cerebellomedullary cistern is easily accessible to a needle introduced anterosuperiorly through the posterior atlanto-occipital membrane, between the posterior arch of atlas and the posterior margin of the foramen magnum. Therefore, it is utilized for **cisternal puncture** if lumbar puncture is not possible to withdraw CSF by clinicians for therapeutic and diagnostic purposes.
  - This cistern is triangular in sagittal section. It is the only cistern which directly communicates with the ventricular system of the brain through openings (*foramen of Magendie and foramina of Luschka*) in the roof of the 4th ventricle.
2. **Pontine cistern (cisterna pontis)**: This is an extensive subarachnoid space on the ventral surface of the pons and contains

the basilar artery and its branches. It is continuous below with the subarachnoid space of the spinal cord, behind with the cerebellomedullary cistern and rostrally with the interpeduncular cistern.

3. **Interpeduncular cistern (basal cistern):** It is formed by the arachnoid mater bridging across the two temporal lobes on the inferior aspect of the brain and contains the circle of Willis (*circulus arteriosus* ).
  - Interpeduncular cistern is continuous laterally with the subarachnoid spaces surrounding the middle and posterior cerebral arteries, and anteriorly with the subarachnoid spaces around the anterior cerebral arteries.
4. **Cistern of lateral sulcus/fossa (Sylvian cistern):** It lies in front of each temporal pole and is formed by the arachnoid mater bridging the lateral sulcus. It contains the middle cerebral artery.
5. **Cistern of great cerebral vein (cisterna superior or cisterna ambiens):** It occupies the interval between the splenium of corpus callosum and the superior surface of cerebellum. This cistern contains the great cerebral vein of Galen and pineal gland and is widely used as a **neurosurgical landmark** .

### **N.B.**

The various cisterns are large pools of CSF and communicate freely with each other. The pulsations of arteries within CSF help to force the CSF from cisterns onto the superolateral surfaces of the cerebral hemispheres and then into arachnoid villi and granulations.

## **Cerebrospinal fluid (CSF) AN 56.2**

The CSF is a modified tissue fluid which appears clear and watery. It is somewhat similar to blood plasma and interstitial fluid. It is present in the ventricular system within the CNS and in the subarachnoid space surrounding the CNS. It bathes both the external and internal surfaces of the brain and spinal cord, and provides a protective cushion between the CNS and the surrounding bones.

In an adult, the total volume of CSF is approximately 150 ml; of which only 30 ml is in the ventricular system and the remainder in the subarachnoid space.

## Production

Approximately 80–90% of the CSF is produced by the choroid plexuses within the lateral ventricles, with remaining being produced by the choroid plexuses in the 3rd and 4th ventricles. The process of production whether by secretion, filtration or dialysation is uncertain. The average amount of CSF formed per day is approximately 500 ml.

## Circulation and absorption (Fig 23.7 )

From lateral ventricles it passes through the interventricular foramina (of Monro) into the 3rd ventricle, and then via cerebral aqueduct into the 4th ventricle. From here, the fluid escapes via the median aperture (foramen of Magendie) and lateral apertures (foramina of Luschka) in the roof of the fourth ventricle, into the cerebellomedullary and pontine cisterns, respectively.

From these sites, the fluid flows slowly in the subarachnoid space over the brain and spinal cord.

Most of the CSF flows upward through the gap in the tentorium cerebelli and then forward, laterally over the inferior surface of the cerebrum. Finally, it ascends on the superolateral aspect of each cerebral hemisphere to reach the arachnoid villi and granulations which penetrate into the superior sagittal sinus. The CSF enters into the bloodstream of the sinus through the mesothelial cell lining of these villi and granulations.

Some of the CSF moves inferiorly in the subarachnoid space around the spinal cord and cauda equina. Small amount of absorption may also occur into the pial veins.

The flow of CSF is facilitated by the pulsations of cerebral and spinal arteries present in the subarachnoid space and the movements of the head and spine.

The circulation of CSF is summarized in [Flowchart 23.1](#) .

**FLOWCHART 23.1** ■ Circulation of CSF.

## Functions

The CSF performs the following functions:

1. It serves as a cushion between the CNS and the skull.
2. It acts as a shock absorber, i.e., it dampens the transmission of jarring or shocking forces to the CNS.
3. Allows the brain and spinal cord to become buoyant (i.e. float) and thus reducing their effective weight. Therefore, in real life a person does not feel weight of brain in head as it becomes 40–50 gm only.

### CLINICAL CORRELATION AN 63.2

**Hydrocephalus:** *The hydrocephalus* is an abnormal increase in the volume of cerebrospinal fluid (CSF) within the skull.

- **Types of hydrocephalus:** Two varieties of hydrocephalus are described: (1) noncommunicating and (2) communicating.
  - If the CSF accumulates within the ventricular system, the condition is called **internal (noncommunicating) hydrocephalus**. It occurs because of blockage at some point between its site of formation at the choroid plexuses and its site of exit through the foramina in the roof of the 4th ventricle.
  - If the CSF accumulates in the subarachnoid space, the condition is called **external (communicating) hydrocephalus**, as there is no obstruction within or to the outflow from the ventricular system. It commonly occurs because of blockage of arachnoid villi and granulations.
- *Clinical features of hydrocephalus in infants and children (Fig. 23.8):*
  - Disproportionate large size of the head (increased skull circumference)
  - Bossing of the forehead
  - Widely separated cranial sutures
  - Enlarged and tense anterior fontanelle
  - Thin scalp with dilated scalp veins
  - Eyes look downward giving a typical *setting-sun appearance*
  - *Cracked-pot sound* on skull percussion.

### N.B.

*Congenital hydrocephalus* is when the baby is born with an excessive accumulation of CSF in the brain. The causes include stenosis of cerebral

aqueduct, spina bifida, and so on.

The *acquired hydrocephalus* develops at the time of birth or at some point later.

**FIG. 23.8** ■ Clinical features of hydrocephalus.

### **Golden Facts to Remember**

• <b>Largest part of the brain</b>	Cerebrum
• <b>Second largest part of the brain</b>	Cerebellum
• <b>Most of the CSF is formed by</b>	Choroid plexuses of the lateral ventricles
• <b>Narrowest cavity within the brain</b>	Cerebral aqueduct (aqueduct of Sylvius)
• <b>Main blood vessels of the brain and their principal branches lie in the</b>	Subarachnoid space
• <b>Part of the brain which is almost entirely hidden from view by the cerebral</b>	Diencephalon

<b>hemispheres</b> <b>• Largest cistern</b>	Cerebello-medullary cistern
<b>• Only communication between the cavities of the brain and subarachnoid space around brain and spinal cord is through</b>	Three small openings in the roof of the 4th ventricle
<b>• Location of CSF in relation to brain</b>	Inside the brain in ventricular system and outside the brain in subarachnoid space
<b>• Weight of brain is not felt in life</b>	Floats in the CSF, which makes the weight of brain only 50 gm due to buoyancy

## CLINICAL CASE STUDY

A 2-year and 6-month-old boy was taken by his mother to a neurologist and complained that the size of head of her son is unusually large and his eyes look different from other children. On examination, the neurologist found enlarged and tense anterior fontanelle, widely separated cranial sutures, and typical setting-sun appearance of the eyes. He made the diagnosis of **hydrocephalus**.

### Questions

1. What is hydrocephalus?
2. Enumerate the openings through which cavities within the brain communicate with the subarachnoid space around the brain and spinal cord.
3. What is the difference between internal and external hydrocephalus?

### Answers

1. Abnormal increase in the volume of cerebrospinal fluid (CSF) within the skull.
2. Foramen of Magendie (median aperture) and foramina of Luschka (lateral apertures) in the roof of the 4th ventricle.
3. *Internal hydrocephalus*: Excessive accumulation of CSF within the ventricular system of brain.

*External hydrocephalus:* Excessive accumulation of CSF in the subarachnoid space around the brain.

---

# Chapter 24: Brainstem and functional column of cranial nerve nuclei

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Draw labelled diagrams to show external features on dorsal and ventral aspects of brainstem.
- Describe external features of medulla oblongata. **AN 58.1**
- Describe the transverse sections of medulla at the level of: (1) pyramidal decussation, (2) sensory decussation and (3) inferior olivary nucleus. **AN 58.2**
- Enumerate cranial nerve nuclei in medulla oblongata with their functional group. **AN 58.3**
- Describe the anatomical basis and effects of medial and lateral medullary syndrome. **AN 58.4**
- Describe external features of pons. **AN 59.1**
- Draw the labelled diagrams of transverse sections of pons at the level of lower and upper parts. **AN 59.2**
- Enumerate cranial nerve nuclei in pons with their functional group. **AN 59.3**
- Describe the external and internal features of midbrain. **AN 61.1**
- Describe the internal features of midbrain at the level of superior and inferior colliculi. **AN 61.2**
- Describe the anatomical basis of effects of Benedikt's and Weber's syndrome. **AN 61.3**

The brainstem is the stalk-like part of the brain which connects the forebrain (diencephalon and cerebrum) with the spinal cord. It consists, from below upward, of the medulla oblongata, pons, and midbrain.

The brainstem consists of nerve fibres and nerve cells. Most of the fibres in the brainstem are arranged longitudinally in the form of tracts as in the spinal cord. The nerve cells like spinal cord do not form a single central mass of grey matter; rather most of them are aggregated to form well-defined nuclei.

The brainstem nuclei are of the following two types:

1. Nuclei of last 10 cranial nerves (i.e., 3rd–12th cranial nerves)
2. Other named nuclei such as red nucleus, substantia nigra, pontine nuclei, and olivary nuclei

In addition to well-defined tracts and nuclei, the brainstem consists of the diffuse system of cells and fibres called **reticular formation**. Some of the cells of reticular formation form **vital centres**, namely, cardiac, respiratory, vasomotor, and so on. Although these centres are not anatomically demonstrable, they are of great physiological importance.

The external features of the brainstem are shown in [Figures 24.1](#) and [24.2](#).

**FIG. 24.1 ■** External features on the anterior (ventral) aspect of the brainstem.

**FIG. 24.2 ■** External features on the posterior (dorsal) aspect of the brainstem.

The cranial nerve nuclei in brainstem and their functional columns are given on page 363.

## Medulla oblongata

The medulla oblongata is the direct upward continuation of the spinal cord, extending from the foramen magnum to the upper border of the pons. It forms the lowest part of the brainstem and lies almost vertically in the anterior part of the posterior cranial fossa between the clivus (superior surface of the basiocciput) in front and the vallecula of the cerebellum behind.

Medulla provides attachment to the last four cranial nerves.

The lower part of the medulla, like the spinal cord, contains the central canal. In the upper part of the medulla, this canal widens and moves dorsally

to form the lower part of the 4th ventricle. Thus, the medulla is divided into two parts: a **lower closed part** of medulla and an **upper open part** .

### **External features AN 58.1**

The medulla is divided into right and left symmetrical halves by the **anterior median fissure** and **posterior median sulcus** .

The anterior median fissure is continuous below with the corresponding fissure on the spinal cord and above it ends into a small triangular depression called the **foramen caecum** at the lower border of the pons. It is interrupted in its lower part by the bundles of fibres crossing obliquely from one side to the other, the **decussation of pyramids** .

The posterior median sulcus continues below with the corresponding sulcus of the cord and is present only in the lower half of the medulla. Above, its lips diverge to form the boundaries of a triangular area, the lower part of the floor of the 4th ventricle.

Each half of the medulla is marked by two sulci, anterolateral and posterolateral, which are direct upward continuations of the corresponding sulci of the cord.

The anterolateral sulcus extends along the lateral border of the pyramid, and the rootlets of the hypoglossal (12th cranial) nerve emerge along it.

The posterolateral sulcus lies between the olive and the inferior cerebellar peduncle, and the rootlets of the glossopharyngeal (9th), vagus (10th), and cranial root of accessory (11th) cranial nerves emerge along it.

### **Features on the ventral aspect**

The ventral aspect of medulla presents the following features:

1. **Pyramids:** These are two elongated elevations, one on either side of the anterior median fissure, and are produced by the underlying corticospinal (pyramidal) fibres.
2. **Olives:** These are oval elevations, posterolateral to the pyramids and are produced by an underlying mass of grey matter called *inferior olivary nucleus* .
3. **Rootlets of the hypoglossal nerve:** These emerge from the anterolateral sulcus between the pyramid and the olive.
4. **Inferior cerebellar peduncles:** These are thick bundles of fibres lying posterolateral to the olive and attach medulla with the cerebellum.

5. **Rootlets of the 9th, 10th, and 11th (cranial part) cranial nerves:** These emerge through the posterolateral sulcus separating the olive from the inferior cerebellar peduncle.

### **Features on the dorsal aspect**

The dorsal aspect of the medulla is well demarcated into lower closed and upper open parts.

### **Features of the closed part**

The closed part, on either side of the posterior median sulcus, presents three longitudinal elevations. From medial to lateral these are fasciculus gracilis, fasciculus cuneatus, and inferior cerebellar peduncle. The upper ends of the fasciculus gracilis and fasciculus cuneatus expand to form the gracile and cuneate tubercles, respectively, because of underlying nuclei of the same name.

Another elevation present lateral to cuneate tubercle; the **tuber cinereum** is produced by the spinal nucleus of the trigeminal nerve.

### **Features of the open part**

The open part of the medulla forms the lower part of the floor of the 4th ventricle which presents a number of features such as median sulcus, hypoglossal and vagal triangles, vestibular areas, area postrema, and stria medullaris (for details, see floor of the 4th ventricle in [Chapter 25](#) , page 369).

### **Internal structure**

The internal structure of medulla is well appreciated by examining its transverse sections (TS) at the following three levels:

1. At the level of decussation of pyramids
2. At the level of sensory decussation
3. At the level of the olives.

### **TS of medulla at the level of decussation of pyramids AN 58.2**

The transection at this level passes through the inferior half of the medulla and closely resembles that of the spinal cord. However, following important features are observed at this level ([Fig. 24.3](#)):

1. The **nucleus gracilis** and **nucleus cuneatus** appear as narrow strip-

- like projections from the posterior aspect of the central grey matter.
2. The apex of posterior horn swells up to form the nucleus of the spinal tract of the trigeminal nerve.
  3. The **spinal tract of the trigeminal nerve** is a bundle of fibres, which caps the nucleus of the spinal tract of the trigeminal nerve.
  4. **Decussation of pyramidal tracts forms the most important feature of medulla at this level** . Approximately 75% fibres of pyramidal tract run backward and laterally across the midline to reach the lateral white column of the opposite side of the spinal cord where they run downward as the lateral corticospinal tract. In doing so, the anterior horns are detached from the central grey matter.
  5. Each detached anterior horn divides to form the spinal nucleus of the accessory nerve and the supraspinal nucleus of the 1st cervical nerve.
  6. Diffuse zone appears containing a network of fibres and scattered nerve cells within it, in the lateral white column adjacent to the nucleus of the spinal tract of the trigeminal nerve is called **reticular formation** .

**FIG. 24.3** ■ Transverse section of medulla at the level of pyramidal decussation.

## TS of medulla at the level of sensory decussation AN 58.2

This section passes through the middle of medulla and displays the following features ([Fig. 24.4](#)):

1. The **nucleus gracilis** and **nucleus cuneatus** become more pronounced and are separated from the central grey matter. The fibres of fasciculus gracilis and fasciculus cuneatus terminate in these nuclei.
2. The **internal arcuate fibres** arising from gracile and cuneate nuclei course forward and medially around the central grey matter and decussate with corresponding fibres of opposite side in the median plane (*sensory decussation*) and then turn upward to ascend as the *medial lemniscus* on the opposite side close to the median plane.
3. The **internal arcuate fibres** cut off the spinal nucleus and tract of the trigeminal nerve from the central grey matter.
4. Immediately dorsolateral to the cuneate nucleus lies the **accessory cuneate nucleus** which receives the more lateral fibres (derived from the cervical segments of the cord) of the fasciculus cuneatus and gives rise to posterior external arcuate fibres conveying proprioceptive impulses to the cerebellum of the same side through inferior cerebellar peduncle.
5. The separated **spinal nucleus** and **tract of trigeminal nerve** lies ventrolateral to the cuneate nucleus.
6. The lower part of **inferior olivary nucleus** is seen.
7. The **pyramids** lie on either side of the anterior median fissure.
8. The central grey matter contains: (1) hypoglossal nucleus, (2) dorsal nucleus of vagus, and (3) nucleus of tractus solitarius.
9. The **medial longitudinal bundle/fasciculus** lies posterior to the medial lemniscus. It is a small compact tract of nerve fibres which interconnect the 3rd, 4th, 6th, 8th, and spinal nucleus of the 11th cranial nerve nuclei.
10. **Spinocerebellar** and **lateral spinothalamic tracts** lie in the anterolateral area of lateral white column.
11. **Lateral** and **anterior spinothalamic tracts** are very close to each other and collectively form **spinal lemniscus**.

**FIG. 24.4 ■** Transverse section of medulla at the level of sensory decussation. 1, nucleus tractus solitarius; 2, dorsal nucleus of vagus; 3, hypoglossal nucleus; M, medial longitudinal fasciculus; R, reticular formation.

### **TS of medulla at the level of olives/upper part AN 58.2**

Transverse section passes across the floor of the 4th ventricle and through the middle of olives and presents the following features ([Fig. 24.5](#)):

**FIG. 24.5 ■** Transverse section of medulla at the level of olives. M, medial longitudinal bundle; R, reticular formation; T, tectospinal tract.

This passes through the floor of the 4th ventricle and through the middle of olives and presents the following features ([Fig. 24.5](#)):

1. The central grey matter is spread over the floor of the 4th ventricle and contains the nuclei of several cranial nerves. From medial to lateral, these are **hypoglossal nucleus, nucleus intercalatus, dorsal nucleus of vagus**, and **vestibular nuclei** (inferior and medial).
2. The **nucleus of tractus solitarius** lies ventral to vestibular nuclei.
3. The **nucleus ambiguus** lies deep within the reticular formation and gives origin to the motor fibres of 9th, 10th, and 11th cranial nerves.
4. On either side of the midline (paramedian region) from dorsal to ventral lie medial longitudinal fasciculus (MLF), tectospinal, medial lemniscus, and pyramidal (corticospinal) tracts.
5. The **arcuate nuclei**, thought to be inferiorly displaced pontine nuclei, are situated on the anteromedial aspect of the pyramids.
6. Laterally, from dorsal to ventral lie two prominent structures: (1)

**inferior cerebellar peduncle** and (2) **inferior olivary nucleus** .

- The *inferior cerebellar peduncle* occupies posterolateral part.
- The *inferior olivary nucleus* is the largest mass of grey matter, and forms the most prominent feature in the section through the upper part of medulla. It presents crumpled bag-like appearance. Medial and dorsal accessory olivary nuclei lie close to the main nucleus.

**N.B.**

Transverse section of medulla just inferior to the pons presents same features as those seen in the transverse section of medulla at the level of the olives, except that:

- The *lateral vestibular nucleus* replaces the inferior vestibular nucleus.
- The *cochlear nuclei* are now visible. The dorsal and ventral cochlear nuclei lie on dorsolateral and ventrolateral aspects of the inferior cerebellar peduncle, respectively.

The cranial nerve nuclei present in medulla oblongata are summarized in [Table 24.1](#) .

**Cranial nerve nuclei in medulla**

The medulla contains nuclei of last four cranial nerves.

The cranial nerve nuclei located in medulla and their functional groups are given in [Box 24.1](#) .

**BOX 24.1**

**Cranial nerve nuclei located in medulla and their functional groups**

Cranial nerve nuclei	Functional groups
Hypoglossal nucleus (XII)	General somatic efferent (GSE)
Nucleus ambiguus (IX, X, and XI)	Special visceral efferent (SVE)
Dorsal nucleus of vagus (X)	General visceral efferent (GVE) column
Nucleus tractus solitarius (IX and X)	Special visceral afferent (SVA)/general visceral afferent (GVA)
Inferior salivatory nucleus	General visceral efferent (GVE)

(IX)	
Spinal nucleus of trigeminal nerve (V)	General somatic afferent (GSA)

## Arterial supply of the medulla AN 58.2

The medulla is supplied by the following arteries:

1. Two vertebral arteries
2. Anterior and posterior spinal arteries
3. Posterior inferior cerebellar arteries.

## CLINICAL CORRELATION AN 58.4

### Lesions of medulla oblongata ( Fig. 24.6 )

- **Lateral medullary (posterior inferior cerebellar artery) syndrome of Wallenberg:** It occurs because of thrombosis of the posterior inferior cerebellar artery, thus *affecting a wedge-shaped area on the dorsolateral aspect of the medulla* and the inferior surface of the cerebellum, and produces the following main signs and symptoms:
  - ¢(1) Contralateral loss of pain and temperature sensation in the trunk and limbs, due to involvement of spinothalamic tract.
  - ¢(2) *Ipsilateral loss of pain and temperature sensation over the face* , due to involvement of the spinal nucleus and tract of the trigeminal nerve.
  - ¢(3) Ipsilateral paralysis of muscles of palate, pharynx and larynx, due to involvement of nucleus ambiguus.
  - ¢(4) *Ipsilateral ataxia* , due to involvement of inferior cerebellar peduncle and cerebellum.
  - ¢(5) *Giddiness* , due to involvement of vestibular nuclei.
- **Medial medullary syndrome:** It occurs because of *involvement of the paramedian region of the medulla* following damage to penetrating branches of the anterior spinal branch of the vertebral artery. It produces following signs and symptoms:
  - ¢(a) Contralateral hemiplegia/paralysis of arm and leg, due to damage of pyramid.
  - ¢(b) Ipsilateral paralysis and atrophy of the half of the tongue, due to damage of hypoglossal nerve.
  - ¢(c) Contralateral loss of position and vibration sense, due to damage of

medial lemniscus.

**FIG. 24.6 ■** Lesions of medulla oblongata involving dorsolateral part and paramedian regions in lateral and medial medullary syndromes respectively.

## Pons

The pons is a bulky broad transverse mass of the brainstem between the midbrain and medulla.

On either side, the pons is continuous as the middle cerebellar peduncle, thus forming a bridge between the two cerebellar hemispheres, hence its name pons (Latin, *pons* = bridge).

## External features AN 59.1

The pons has **two surfaces** : ventral and dorsal, and **two borders** : superior and inferior.

### Features on the ventral aspect

The ventral surface of pons is **convex** in both the directions, i.e., from before backward and from side to side. It is transversely striated because of underlying pontocerebellar fibres.

In the median plane, it presents a vertical groove, the **basilar groove** which lodges the basilar artery.

The **trigeminal nerve** is attached to this surface by two roots: a small motor and a large sensory root (the motor root lies medial to the sensory root).

Rostrally, the junction between the midbrain and pons is marked by **cerebral peduncles** and the intervening interpeduncular fossa; caudally the pontomedullary junction is marked by a shallow groove. In this groove, from medial to lateral, the abducent (6th), facial (7th), and vestibulocochlear (8th) nerves emerge.

The superior cerebellar arteries curve along the superior border, intervening between the oculomotor and trochlear nerves. The anterior inferior cerebellar arteries curve around the inferior border.

### Features on the dorsal aspect

The dorsal surface of the pons is covered by the cerebellum and separated from it by the cavity of the 4th ventricle. The dorsal surface of the pons is triangular and forms the upper part of the floor of the 4th ventricle. For details of features on the dorsal surface of pons, see the floor of the 4th ventricle described in detail in [Chapter 25](#) .

## Internal structure

A cross-section at any level of pons shows two distinct regions:

1. A large ventral or **basilar part**
2. A small dorsal or **tegmental part** .

The **ventral or basilar part** is continuous inferiorly with the pyramids of the medulla and on each side with the middle cerebellar peduncle.

The **dorsal or tegmental part** is a direct upward continuation of the

medulla excluding the pyramids.

*The structure of basilar part is same at all levels of pons, but the structure of tegmental part varies considerably in the upper and lower parts of the pons.*

## Basilar part

Basilar part is composed of the longitudinal bundles of fibres, the transverse fibres and the pontine nuclei:

1. **Longitudinal bundles of fibres** include corticopontine, corticonuclear, and corticospinal fibres.
  - (a) The *corticopontine fibres* relay in the ipsilateral pontine nuclei.
  - (b) The *corticonuclear fibres* terminate in the contralateral (and to some extent ipsilateral) motor nuclei of the cranial nerves.
  - (c) The *corticospinal fibres* converge towards the lower part of the pons and form the pyramids of the medulla.
2. **Transverse fibres** arise in the pontine nuclei and cross to the opposite side to form the middle cerebellar peduncle. These are *pontocerebellar fibres*.
3. **Pontine nuclei** are scattered among the longitudinal and transverse fibres.

## Tegmental part

Tegmental part is traversed by a number of ascending and descending tracts and contains a decussation of transversely running fibres, the **trapezoid body**. It also contains the nuclei of trigeminal (5th), abducent (6th), facial (7th), and vestibulocochlear (8th) nerves.

Because the structure of tegmentum differs in the lower (caudal) and upper (cranial) parts of the pons, it is studied by examining transverse sections at these two levels.

## TS through lower part of the pons AN 59.2

Transverse section through the lower part of the pons passes through the facial colliculi (Fig. 24.7).

**FIG. 24.7** ■ Transverse section through the lower part of the pons. M, medial longitudinal bundle; R, rubrospinal tract; T, tectospinal tract; S= superior salivatory nucleus

The tegmentum at this level presents the following features.

### Grey matter

The grey matter at this level comprises:

1. The *abducent nerve nucleus* lying beneath the facial colliculus in the floor of the 4th ventricle.
2. The **motor nucleus of the facial nerve** lying ventrolateral to the abducent nucleus. The fibres of the facial nerve first wind round the abducent nucleus, producing the **facial colliculus**, then pass anteriorly between the facial nucleus and the nucleus of the spinal tract of the trigeminal nerve.

3. The **superior salivatory, inferior salivatory, and lacrimate nuclei** lying medial to the motor nucleus of the facial nerve.
4. The **nucleus of tractus solitarius** lying lateral to the superior salivatory nucleus.
5. The **vestibular nuclei** lying beneath the vestibular area in the floor of the 4th ventricle.
6. The **dorsal and ventral cochlear nuclei** situated dorsal and ventral to the inferior cerebellar peduncle, respectively.
7. The **spinal nucleus of the trigeminal nerve and its tract** located on the anteromedial aspect of the inferior cerebellar peduncle.

### White matter

The white matter at this level comprises:

1. The **trapezoid body** that is a trapezium-shaped mass of white fibres lying in the anterior part of the tegmentum, just posterior to the basilar part of the pons. It is formed by the decussation of transversely running fibres arising from the cochlear nuclei of both the sides.
2. The **medial lemniscus** situated in the most anterior part of the tegmentum with its long axis running transversely.
3. The **spinal lemniscus** lying lateral to the medial lemniscus and occupying the same peripheral position as in the medulla.
4. The **medial longitudinal bundle** occupying a paramedian position in the most posterior part.
5. The **tectospinal tracts** located ventral to the medial longitudinal bundles.
6. The **spinal tract of the trigeminal nerve** lying lateral and dorsal to the motor nucleus of the facial nerve.

### TS through upper part of the pons (Fig. 24.8 ) AN 58.2

Transverse section through the upper part of the pons passes through the trigeminal nuclei.

**FIG. 24.8 ■** Transverse section through the upper part of the pons, M, medial longitudinal bundle; T, tectospinal tract; R, rubrospinal tract.

The tegmentum at this level presents the following features.

### Grey matter

The grey matter at this level comprises:

1. The **motor nucleus of trigeminal nerve** situated in the dorsolateral part, beneath the lateral part of the 4th ventricle. The emerging motor fibres travel anteriorly through the substance of the pons and exit on its anterior surface.
2. The principal (main) sensory nucleus of the trigeminal nerve situated lateral to the motor nucleus.

### White matter

The white matter at this level consists of the same ascending tracts as in the lower part. However, the **lateral lemniscus** is well formed here. The spinal lemniscus lies between the medial and lateral lemnisci.

The **trigeminal lemniscus** consisting of trigeminothalamic fibres is also seen between medial lemniscus and spinal lemniscus.

### **N.B.**

The ventral part of tegmentum, immediately posterior to the basilar part, presents four lemnisci. From medial to lateral side, these are medial lemniscus, trigeminal lemniscus, spinal lemniscus, and lateral lemniscus.

### **Cranial nerve nuclei in pons AN 59.3**

The pons contains nuclei of 5th, 6th, and 7th cranial nerves.

The cranial nerve nuclei is located in pons and their functional groups are given in the [Box 24.2](#) .

### **BOX 24.2**

#### **Cranial nerve nuclei located in pons and their functional groups**

<b>Cranial nerve nuclei</b>	<b>Functional column/group</b>
• Motor nucleus of facial nerve (VII)	Special visceral efferent (SVE)
• Motor nucleus of abducent nerve (VI)	General somatic efferent (GSE)
• Motor nucleus of trigeminal nerve (V)	Special visceral efferent (SVE)
• Chief sensory & spinal nuclei of trigeminal nerve (V)	General somatic afferent (GSA)
• Lacratory and superior salivatory nuclei	General visceral efferent (GVE)

### **Arterial supply**

The pons is supplied by the following arteries:

1. Numerous (pontine) branches from the basilar artery
2. Anterior inferior cerebellar artery.

## CLINICAL CORRELATION

**Millard–Gubler syndrome:** It results from a lesion in the lower part of the pons which is so placed that it includes the pyramidal tract and the emerging fibres of the abducent and facial nerves.

The characteristic features of this syndrome are as follows:

- *Ipsilateral medial squint*, due to involvement of the abducent nerve
- *Ipsilateral facial palsy*, due to involvement of facial nerve fibres
- *Contralateral hemiplegia*, due to involvement of the corticospinal tract.

For other lesions, see *Textbook of Clinical Neuroanatomy*, 4ed. by Vishram Singh.

## Midbrain

The midbrain is the shortest segment of the brainstem. It connects the pons to the diencephalon and cerebrum. Its cavity, the **cerebral aqueduct (aqueduct of Sylvius)** connects 3rd ventricle with the 4th ventricle.

### External features AN 61.1

#### Features on the ventral aspect

The ventral surface of the midbrain presents two **crurs cerebri** which emerge from the cerebral hemispheres and converge downward to enter the pons forming the posterolateral boundaries of the interpeduncular fossa.

The superficial surface of the crus cerebri is finely corrugated by the underlying longitudinal fibres.

The oculomotor nerve emerges on either side from a groove on the medial side of the crus cerebri.

#### Features on the dorsal aspect

The dorsal surface of the midbrain presents four rounded elevations: two superior and two inferior colliculi (or *corpora quadrigemina*). The colliculi are separated from each other by a cruciform sulcus. The vertical limb of sulcus when traced above forms a surface depression which lodges the **pineal body** and when traced below, it becomes continuous with the **frenulum veli** (a median ridge on the dorsal surface of *superior medullary velum*).

The trochlear nerves emerge one on each side of the upper part of frenulum

veli after decussation in the superior medullary velum. Thick ridges of white matter extending from the lateral side of each colliculus constitute their brachia.

The **superior brachium** connects the superior colliculus to the lateral geniculate body and the optic tract. It is made up of optic tract fibres (retinotectal tract). The **inferior brachium** connects the inferior colliculus to the medial geniculate body, and is made up of auditory fibres.

### **Internal structure/features AN 61.1**

The internal structure of the midbrain is studied conveniently by examining its transverse sections. The transverse section of the midbrain shows a tiny canal, called **cerebral aqueduct**. A coronal plane passing through the aqueduct divides the midbrain into two parts: a small posterior part and a large anterior part.

The small posterior part is called **tectum** and consists of four colliculi. The large anterior part is divided into two equal right and left halves, the **cerebral peduncles** by a vertical plane. Each cerebral peduncle is further subdivided into three parts; from dorsal to ventral, these are: (1) tegmentum, (2) substantia nigra, and (3) crus cerebri.

The structures in the tectum and tegmentum vary at different levels of the midbrain, but those of the crus cerebri and substantia nigra are nearly the same throughout the length of the midbrain.

### **Crus cerebri (basis pedunculi)**

The crus cerebri is the part of the cerebral peduncle situated anterolateral to substantia nigra. It contains important descending tracts which connect the cerebral cortex to the anterior horn cells of the spinal cord, cranial nerve nuclei, and pontine nuclei.

### **Substantia nigra**

The substantia nigra is a curved (crescent-shaped) pigmented band of grey matter (thicker medially than laterally) situated between tegmentum and crus cerebri. Its concavity is smooth and directed towards the tegmentum.

The substantia nigra is made up of deeply pigmented nerve cells which contain melanin (a polymerized form of dopamine) and iron.

The structure of tectum and tegmentum vary at different levels; therefore, it is again best studied by examining the TS of the midbrain at the following two levels: (1) at the level of the inferior colliculi and (2) at the level of

superior colliculi.

### TS of midbrain at the level of inferior colliculi AN 61.2

The grey and white matter at this level present the following features (Fig. 24.9 ):

**FIG. 24.9** ■ Transverse section of the midbrain at the level of inferior colliculi. M, medial longitudinal bundle; R, rubrospinal tract; T, tectospinal tract.

### Grey matter

1. The central grey matter (grey matter around the cerebral aqueduct) contains two nuclei: (1) the nucleus of the trochlear nerve and (2) the mesencephalic nucleus of the trigeminal nerve.
  - ⊖ The *trochlear nerve nucleus* is situated close to the median plane just posterior to the MLF. The emerging fibres of the trochlear nerve pass laterally and posteriorly around the central grey matter and leave the midbrain just below the inferior colliculi. The fibres of the trochlear nerve now decussate before emerging on the surface.

- The *mesencephalic nucleus of the trigeminal nerve* lies in the lateral edge of the central grey matter.
- 2. An ovoid mass of grey matter underneath the inferior colliculus forms the **nucleus of inferior colliculus** .

## White matter

1. The **decussation of the superior cerebellar peduncles** occupies the central part of the tegmentum and forms the most important feature in the lower part of the midbrain.
2. The **lemnisci** are arranged in the form of a curved compact band of white fibres in the ventrolateral part of the tegmentum, lateral to cerebellar decussation and dorsal to the substantia nigra. From medial to lateral side, these are *medial lemniscus, trigeminal lemniscus, spinal lemniscus, and lateral lemniscus*.
3. The **MLF** lies on the side of the median plane ventral to the trochlear nerve nucleus.

## TS of midbrain at the level of superior colliculi AN 61.2

The grey and white matter in the midbrain at this level present the following features ([Fig. 24.10](#)):

**FIG. 24.10** ■ Lesions of midbrain involved in Weber and Benedikt syndromes.

## Grey matter

1. The **central grey matter** in each half contains two nuclei: the oculomotor nerve nucleus and the mesencephalic nucleus.
  - ⊖ The *oculomotor nerve nucleus* lies in the ventromedial part. The nuclei of two sides fuse together forming a single complex having a triangular outline. The emerging fibres of oculomotor nerve pass ventrally through the tegmentum, intersecting red nucleus and medial part of the substantia nigra, and emerge in the posterior part of the interpeduncular fossa through the sulcus on the medial aspect of crus cerebri.
  - ⊖ The *mesencephalic nucleus* occupies the same position as in the lower part of the midbrain.
2. The nucleus of **superior colliculus** consists of cells which are involved in *general light reflexes* .
3. **Pretectal nucleus** is a small group of nerve cells and lies deep to the

superolateral part of the superior colliculus.

4. **Red nucleus** is a cigar-shaped mass of grey matter which appears ovoid in cross-section. It is approximately 0.5 cm in diameter. It is situated in the tegmentum, ventral to the 3rd nerve nucleus, and dorsomedial to the substantia nigra. It is an important nucleus of the extrapyramidal system.

## White matter

1. Decussation of fibres (tectospinal and tectobulbar tracts) arising from superior colliculi forming **dorsal tegmental decussation (of Meynert)** .
2. Decussation of fibres (rubrospinal tracts) arising from red nuclei forming **ventral tegmental decussation (of Forel)** .
3. **Medial longitudinal fasciculus** lying ventrolateral to the oculomotor nucleus.
4. Tegmentum at this level also containing the same lemnisci (i.e., medial, trigeminal, and spinal) as those at the level of inferior colliculus *except* for the lateral lemniscus.
5. Emerging fibres of the oculomotor nerve.

## Medial longitudinal fasciculus

Medial longitudinal fasciculus is a heavily myelinated composite tract found in the paramedian plane of the brainstem.

*The fibres of MLF interconnect the nuclei of the 3rd, 4th, 6th and 8th cranial nerves, and the spinal nucleus of the accessory nerve.*

*The chief function of MLF is to coordinate the movements of eyes, head, and neck in response to stimulation of the vestibulocochlear nerve.*

## Arterial supply

The midbrain is supplied by the following arteries:

1. Basilar artery through its posterior cerebral and superior cerebellar arteries. Basilar artery also supplies the midbrain through direct branches.
2. Branches of posterior communicating and anterior choroidal arteries.

## CLINICAL CORRELATION

## Lesions of midbrain (Fig. 24.11 )

- **Weber syndrome:** This syndrome is produced by a vascular lesion in the basal region of the cerebral peduncle due to occlusion of a branch of the posterior cerebral artery. This lesion involves the oculomotor nerve and the crus cerebri.

◊ The characteristic features of this syndrome are as follows:

- *Ipsilateral lateral squint*, due to involvement of the 3rd cranial nerve.
- *Contralateral hemiplegia*, due to involvement of corticospinal tract in the crus cerebri. **AN 61.3**

- **Benedikt syndrome:** It occurs because of the vascular ischaemia of the tegmentum of the midbrain, involving medial lemniscus, spinal lemniscus, red nucleus, superior cerebellar peduncle, and fibres of the oculomotor nerve. It is characterized by the following signs and symptoms:

- ◊ *Ipsilateral lateral squint and ptosis*, due to involvement of oculomotor nerve fibres.
- ◊ *Contralateral loss of pain and temperature sensation*, due to involvement of trigeminal and spinal lemnisci.
- ◊ *Contralateral loss of tactile, muscle, joint, and vibration sense*, due to involvement of medial lemniscus.
- ◊ *Contralateral tremors and involuntary movements in the limbs*, due to involvement of the red nucleus and fibres of superior cerebellar peduncle entering into it. **AN 61.3**

**FIG. 24.11** ■ Transverse section of the midbrain at the level of superior colliculi.

## Development of functional columns and nuclei in brainstem

The brain and spinal cord develop from the neural tube. The cranial end of the neural tube forms the brain, whereas the caudal end forms the spinal cord.

The nerve cells in the wall of the neural tube arrange themselves into functional groups.

## Functional groups/columns of cells in the spinal cord

In cross-section, the central canal of spinal cord projects laterally as a groove

on the inner aspect of wall of the spinal cord as **sulcus limitans** which divides the wall of the spinal cord on each side into two parts: dorsal and ventral laminae. The dorsal and ventral laminae are also frequently termed **alar** and **basal laminae** , respectively.

The alar lamina consists of sensory cells and basal lamina consists of motor cells. The cells in each lamina are arranged into two columns: one near the sulcus limitans, concerned with the innervation of viscera, is called the **visceral column** and one away from sulcus limitans, concerned with innervation of somatic structures, is called the **somatic column** .

**Thus, there are four functional columns on either side in the lateral wall of the spinal cord ( Fig. 24.12 )** : two sensory columns in the alar lamina and two motor columns in the basal lamina, namely:

1. General somatic afferent
2. General visceral afferent
3. General somatic efferent
4. General visceral efferent.

**FIG. 24.12 ■** Functional columns in the lateral wall of the spinal cord.

### **Functional columns of cranial nerve nuclei in the brainstem (Fig 24.13 )**

There is a similar arrangement in the brainstem, but here a third type of cell column appears in each lamina between the visceral and somatic column to

innervate the derivatives of pharyngeal arches. This column is termed the **special visceral column** .

Apart from this, an extra **special somatic column** appears in the most lateral part of the alar lamina to innervate the vestibular and cochlear apparatuses. Thus, there are seven functional columns in the brainstem: four in the alar lamina and three in the basal lamina (Fig. 24.13 ), namely:

1. Special somatic afferent (SSA)
2. General somatic afferent (GSA)
3. Special visceral afferent (SVA)
4. General visceral afferent (GVA)
5. General somatic efferent (GSE)
6. Special visceral efferent (SVE)
7. General visceral efferent (GVE).

**FIG. 24.13 ■** Functional columns in the brainstem.

As the development proceeds, each column differentiates into two or more discrete cranial nerve nuclei. The cranial nerve nuclei with their functional components are given in Table 24.1 .

## **TABLE 24.1**

### **Cranial nerve nuclei derived from various functional columns in the brainstem AN 62.1**

GSE column	SVE column	GVE column	GVA/SVA column	GSA column
1. Oculomotor nucleus 2. Trochlear nucleus 3. Abducent nucleus 4. Hypoglossal nucleus	1. Motor nucleus of the trigeminal nerve 2. Motor nucleus of the facial nerve 3. Nucleus ambiguus	1. Dorsal nucleus of the vagus nerve	Nucleus of the solitary tract (nucleus tractus solitarius)	Sensory of the trigeminal nerve – Chief – Mesencephalic – Spinal

## Reticular formation

The reticular formation is a diffuse ill-defined mass of nerve cell clusters and interlacing nerve fibres occupying the entire core of the brainstem.

Phylogenetically, it represents the old reticular core of the brain and contains within it the '*vital centres*'.

Reticular formation extends cranially to the diencephalon and caudally to the spinal cord.

The reticular formation receives data from most of the sensory systems of the body and relay them to all the levels of the neuraxis. It is important for the maintenance of sleep–wake cycle and level of consciousness.

Although reticular formation is described as a network of nerve fibres intermingled with nerve cells, on careful examination, it reveals fairly localized cell groups called *reticular nuclei* in certain regions.

The reticular pathways are polysynaptic, both ascending and descending, and crossed and uncrossed. As a result, unilateral stimulation produces bilateral responses.

## Functional components of reticular formation

Functionally, the reticular formation is divided into subgroups, namely:

1. ***Ascending reticular activating system (ARAS)***
2. ***Descending reticular system (DRS)***

The ARAS is believed to be responsible for the maintenance of alertness and consciousness of the brain. It is generally termed simply a **reticular activating system (RAS)** by clinicians .

The DRS consists of descending pathways to autonomic centres of the brainstem and plays a critical role in regulating the functions of the vital centres, namely, respiratory centre, cardiac centre, and vasomotor centre.

### CLINICAL CORRELATION

**Maintenance of alertness and attention:** The visual and acoustic stimuli can stimulate the reticular activating system and thus maintain alertness and attention.

For this reason, the stimuli such as sound of ringing alarm clock or sudden bright light can arouse consciousness. The sleep is thought to occur because of decrease in the activity of RAS. A coma is a state of unconsciousness due to the inactivity of RAS.

### Golden Facts to Remember

• <b>Most important part of the brain for survival</b>	Medulla oblongata
• <b>All the cranial nerves arise from the brainstem <i>except</i></b>	Olfactory and optic nerves
• <b>Shortest segment of the brainstem</b>	Midbrain
• <b>All the nuclei of the last four cranial nerves are located in the medulla oblongata <i>except</i></b>	Nucleus of spinal part of the accessory (11th) nerve, which is located in the upper five cervical spinal segments
• <b>Most prominent feature in the transverse section of the midbrain at the level of superior colliculi</b>	Presence of red nuclei

<ul style="list-style-type: none"> <li>• <b>Largest segment of brainstem</b></li> <li>• <b>All the cranial nerves arise from the ventral aspect of the brain except</b></li> </ul>	Pons Trochlear nerve which arises from the dorsal aspect of the brain
<ul style="list-style-type: none"> <li>• <b>Nuclei of brainstem which functionally belong to basal nuclei, basal ganglia</b></li> </ul>	Substantia nigra, red nucleus
<ul style="list-style-type: none"> <li>• <b>Most important centres present in the reticular formation</b></li> </ul>	Vital centres (respiratory, cardiac, and vasomotor)

## CLINICAL CASE STUDY

A 55-year-old man went to his family physician and complained that for the past few days he has been having difficulty in walking. He also noted that when he walks, his left arm remains flexed and his left leg remains extended. Furthermore, he has to swing his left lower limb outward to avoid dragging the foot on the ground. His family physician referred him to the neurologist.

On examination, the neurologist found the following: (1) no signs of facial palsy, (2) deviation of tongue to the right side on protrusion, (3) atrophy of tongue on the right side, and (4) loss of position and vibration sense on the left side. A diagnosis of right-sided **medial medullary syndrome** was made.

### Questions

1. Name the area of medulla involved in medial medullary syndrome.
2. What is the commonest cause of this syndrome?
3. Mention the cause of weakness of left arm and left leg (left-sided hemiplegia).
4. What is the cause of loss of position and vibration sense on the left side?

### Answers

1. Paramedian region.
2. Occlusion of anterior spinal artery.
3. Destruction of right pyramid.
4. Destruction of medial lemniscus on the right side.

---

# Chapter 25: Cerebellum and fourth ventricle

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe cerebellum under the following headings: (a) definition and location, (b) subdivisions and their functions, and (c) applied anatomy.
- Describe the external and internal features of cerebellum. **AN 60.1**
- Describe the connections of cerebellar cortex and intercerebellar nuclei. **AN 60.2**
- Describe the anatomical basis of cerebellar dysfunction. **AN 60.3**
- Write short notes on: (a) intracerebellar nuclei, (b) inferior cerebellar peduncle, (c) floor of 4th ventricle, and (d) cerebellar syndrome.
- Describe parts, boundaries, and features of 4th ventricle. **AN 63.1**

## Cerebellum

The cerebellum (Latin, *cerebellum* = little brain) is the largest part of the hindbrain and the second largest part of the brain as a whole. It weighs approximately 150 g. It is located in the posterior cranial fossa underneath the tentorium cerebelli and behind the pons and medulla oblongata. It is separated from the pons and medulla by the cavity of the 4th ventricle ([Fig. 25.1](#)). Its surface is indented by numerous fine slit-like sulci called **fissures**. Between the fissures lie more or less parallel folds called **folia**. In general, the *fissures and folia* of the cerebellum lie transversely from side-to-side across the whole extent of the cerebellum.

**FIG. 25.1** ■ Sagittal section through the brainstem and cerebellum. The *arrow* is in the median aperture of the 4th ventricle.

The cerebellum consists of two hemispheres united in the midline by the vermis.

Each hemisphere of the cerebellum is connected to three parts of the brainstem by large fibre tracts called **cerebellar peduncles**.

The **basic functions of the cerebellum** are as follows:

1. Maintenance of equilibrium
2. Regulation of muscle tone
3. Coordination of somatic motor activities.

The cerebellar disease is manifested by motor disturbances, including inability to stand upright, staggering gait, hypotonia, and failure of coordination.

### External features AN 60.1

The external features of the cerebellum comprise three parts: two surfaces, two notches, and three well-marked fissures ([Fig. 25.2](#)).

**FIG. 25.2** ■ Superior view of the cerebellum. Note the fissures and folia on the surface of the cerebellum.

## Parts

The cerebellum consists of three parts: two large lateral hemispherical lobes, the **cerebellar hemispheres**, and a narrow median worm-like portion, called **vermis**. The superior and inferior aspects of vermis are termed *superior* and *inferior vermis*, respectively. The ridge-like superior vermis is continuous on either side with the superior surface of cerebellar hemisphere imperceptibly. The inferior vermis is more clearly demarcated from the hemispheres in the floor of *vallecula cerebelli*.

## Surfaces

The **superior surface** of the cerebellum is convex. The two cerebellar hemispheres are continuous with each other on this surface. The **inferior surface** presents a deep median notch called **vallecula**, which separates the two cerebellar hemispheres. The floor of the vallecula is formed by the inferior vermis and is limited on each side by *sulcus valleculae* (see Fig. 25.4).

## Notches

The anterior aspect of cerebellum is marked by a wide shallow **anterior**

**cerebellar notch** which accommodates pons and medulla. The **posterior cerebellar notch** is deep and narrow, and lodges the falx cerebelli.

## Fissures

1. The **horizontal fissure** is most conspicuous and runs along the lateral and posterior margins of the cerebellum. It marks the junction between the superior and inferior surfaces of the cerebellum.
2. The **posterolateral fissure** lies on the inferior surface of the cerebellum and separates the *flocculonodular lobe* from the rest of the cerebellum (*corpus cerebelli*) .
3. The V-shaped **fissura prima** on the superior surface cuts the superior vermis at the junction of its anterior two-third and posterior one-third. It divides the corpus cerebelli into *anterior* and *posterior (middle) lobes* .

## N.B.

There are several other fissures which subdivide the vermis and cerebellar hemispheres into lobules and given fanciful names. Most of them are ignored to lessen the complexity of the cerebellum and only those which have a functional or descriptive value are given.

## Subdivisions of the cerebellum

### Anatomical subdivisions

Anatomically, the cerebellum is divided into the following three lobes (Fig. 25.3 ):

1. Anterior
2. Posterior
3. Flocculonodular.

**FIG. 25.3** ■ Anatomical lobes of the cerebellum. P = Pyramid, U = uvula.

### Anterior lobe

It lies on the superior surface anterior to the fissura prima.

### Posterior/middle lobe

It lies between the fissura prima on the superior surface and posterolateral fissure on the inferior surface.

### Flocculonodular lobe

It is the smallest of all and lies on the inferior surface in front of the posterolateral fissure.

### Morphological subdivisions

Based on phylogenetic and functional criteria, the cerebellum is divided into the following three parts:

1. Archicerebellum
2. Paleocerebellum
3. Neocerebellum.

## Archicerebellum (vestibular cerebellum)

Phylogenetically, it is the oldest part of the cerebellum. It consists of flocculonodular lobe and lingula.

The archicerebellum is chiefly vestibular in connections and *concerned with the maintenance of equilibrium, tone, and posture of trunk muscles*.

## Paleocerebellum (spinal cerebellum)

Phylogenetically, it is the next part of the cerebellum to appear. It consists of anterior lobe (except lingula) and pyramid, and the uvula of inferior vermis.

The paleocerebellum is chiefly spinocerebellar in connections and is *concerned with the tone, posture, and crude movements of the limbs*.

## Neocerebellum (cerebral cerebellum)

Phylogenetically, it is the most recent part of the cerebellum to develop. It is made up of middle lobe, the largest part of the cerebellum (except the pyramid and the uvula of inferior vermis).

The neocerebellum is chiefly corticopontocerebellar in connections and is *concerned with the smooth performance of skilled voluntary movements*.

## Internal structure AN 60.1

The cerebellum is made up of a thin surface layer of grey matter, the **cerebellar cortex**, and a **central core** of white matter. Masses of grey matter called **intracerebellar nuclei** are embedded within the central core of white matter.

The cerebellar cortex is folded in such a way that the surface of cerebellum presents a series of parallel transverse **fissures** and intervening narrow leaf-like bands called **folia**. Each folium consists of a slender branched lamina of central core of white matter covered by a thin layer of grey matter. The central core of white matter being arranged in the form of branching pattern of a tree is called **arbor vitae cerebelli** (arbor vitae = tree of life).

## Structure of the cerebellar cortex AN 60.2

The structure of the cerebellar cortex is uniform throughout (homotypical).

Cerebellar cortex consists of the following three distinct layers:

1. Outer molecular layer
2. Intermediate Purkinje cell layer
3. Inner granular layer

## Molecular (plexiform) layer

It mainly consists of numerous dendritic arborizations of Purkinje cells and relatively few nerve cells which are widely spaced. The nerve cells are of two types: (1) the basket cells and (2) the stellate cells.

## Purkinje cell layer

It consists of a single row of large flask-shaped cells, the **Purkinje cells**.

*The outgoing Purkinje axons constitute the sole output from the cerebellar cortex and exert an inhibitory influence on the intracerebellar nuclei.*

## Granular layer

The inner granular layer consists of numerous closely packed small **granule cells**. This layer also contains few large **Golgi cells**.

## Intrinsic neurons of the cerebellar cortex

There are five types of intrinsic neurons in the cerebellar cortex, namely:

1. Purkinje cells
2. Granule cells
3. Stellate cells
4. Basket cells
5. Golgi cells.

*All the intrinsic neurons of cerebellar cortex are inhibitory except granule cells. Such a collection of inhibitory neurons is not found anywhere else in the central nervous system except in the cerebellum.*

## Intracerebellar nuclei AN 60.2

The intracerebellar nuclei (also called central nuclei) are masses of grey matter embedded in the white matter of the cerebellum. On each side of the midline, they are four in number. From lateral to medial side, these are dentate nucleus, emboliform nucleus, globose nucleus, and fastigial nucleus (Fig. 25.4).

1. The **dentate nucleus** is the most prominent of the intracerebellar nuclei and largest in primates, especially in humans. It is the nucleus of *neocerebellum* and therefore receives afferent fibres from it.
2. The **emboliform nucleus** is oval in shape and situated medial to the

dentate nucleus, partially covering its hilum. It is the nucleus of *paleocerebellum*, hence receives afferent fibres from it.

3. The **globose nucleus** is rounded in shape and lies between the emboliform and fastigial nuclei. It has similar connections to that of the emboliform nucleus. The globose and emboliform nuclei together are sometimes referred to as **nucleus interpositus**.
4. The **fastigial nucleus** lies near the midline in the vermis and close to the roof of the 4th ventricle and is the nucleus of archicerebellum, hence receives afferent fibres from the flocculonodular lobe (archicerebellum).

**FIG. 25.4** ■ Transverse section of the cerebellum showing intracerebellar nuclei.

The nuclear connections of the cerebellum are summarized in [Flowchart 25.1](#).

## FLOWCHART 25.1 ■ Nuclear connections of the cerebellum.

### Connections of cerebellar cortex AN 60.2

The main neuronal connections of cerebellar cortex are:

*Afferent connections:*

- ⊖ Cortico-ponto-cerebellar pathway
- ⊖ Spino-cerebellar tracts

*Efferent connections:*

- ⊖ Cerebello-thalamo-cortical pathway
- ⊖ Cerebello-vestibular fibres.

The afferent and efferent fibres of cerebellum form three large bundles of fibres called cerebellar peduncles.

### Cerebellar peduncles

The afferent and efferent fibres of the cerebellum are grouped together on each side into three large bundles called cerebellar peduncles.

The *superior cerebellar peduncle* s connect the cerebellum to the midbrain, the *middle cerebellar peduncles* to the pons, and the *inferior cerebellar peduncles* to the medulla oblongata.

The **inferior cerebellar peduncle** is formed on the posterolateral aspect of the upper half of the medulla oblongata. It consists of a large number of afferent and efferent fibres. *The inferior cerebellar peduncle consists mainly of afferent fibres to the cerebellum from the spinal cord, the olivary nuclei, the reticular formation of the medulla, and the vestibular nuclei and nerve .* It also transmits a few efferent fibres from the cerebellum to the medulla, principally to the vestibular nuclei and reticular formation.

The **middle cerebellar peduncle** is the largest of the three peduncles. It is formed at the posterolateral margin of the pons. *The middle cerebellar peduncle consists of only afferent fibres which arise from the pontine nuclei of the opposite side.*

The **superior cerebellar peduncle** emerges from the anterior cerebellar notch and forms the lateral boundary of the upper half of the 4th ventricle. *It mainly consists of efferent fibres passing from the dentate nucleus to the red*

*nucleus, thalamus, and cerebral cortex of the opposite side. It is the principal efferent pathway from the cerebellum and its fibres arise mainly in the dentate nucleus.*

## Arterial supply of the cerebellum

The cerebellum is supplied by three pairs of cerebellar arteries:

1. **Superior cerebellar artery:** a branch of basilar artery supplies the superior surface of the cerebellum.
2. **Anterior inferior cerebellar artery:** a branch of basilar artery supplies the anterior part of the inferior surface of the cerebellum.
3. **Posterior inferior cerebellar artery:** a branch of vertebral artery supplies the posterior part of the inferior surface of the cerebellum.

### CLINICAL CORRELATION AN 60.3

**CEREBELLAR SYNDROME:** The cerebellar lesions due to trauma, vascular occlusion, tumours, and so on, produce a number of signs and symptoms (**cerebellar dysfunctions**), which together constitute the *cerebellar syndrome*.

*The characteristic signs and symptoms of the cerebellar syndrome are as follows:*

- (a) *Wide-based gait, due to generalized muscular hypotonia*, leading to staggering gait. Poor muscle coordination in arms and legs (ataxia).
- (b) *Intention tremors* at the end of a voluntary act, and disappear with rest.
- (c) *Adiadochokinesis*, i.e., inability to perform rapidly alternating opposite movements, for example, pronation and supination.
- (d) *Dysarthria or scanning speech*, that is, speech is slurred, monotonous with pauses at wrong places.
- (e) *Nystagmus*, that is, involuntary 'to and fro' oscillatory movements of the eyeballs while looking to either side due to defective postural fixation of the conjugate gaze.
- (f) *Swaying* towards the side of lesion on walking.
- (g) Falling on the side of lesion on closing the eyes (*Romberg sign*).

## Fourth ventricle AN 63.1

The 4th ventricle is a diamond-shaped cavity of the hindbrain lined with ependyma and filled with cerebrospinal fluid (CSF). It is situated in the posterior cranial fossa in front of the cerebellum and behind the pons and the upper part of medulla oblongata.

The cavity of the ventricle presents a triangular outline in the sagittal section. It is continuous inferiorly with the central canal of medulla oblongata and superiorly with the cerebral aqueduct of the midbrain ([Fig. 25.1](#)).

The understanding of the 4th ventricle is essential, firstly because it is strategically placed in the midst of **vital structures** present in the medulla, pons, and cerebellum, and secondly because its roof possesses three important openings which permit the CSF to escape from the ventricular system of the brain to the subarachnoid space.

## Boundaries

The boundaries of the 4th ventricle include lateral boundaries, a roof, and a floor.

### Lateral boundaries (lateral walls)

On each side, the 4th ventricle is bounded:

- (a) *Inferolaterally* by the inferior cerebellar peduncle, supplemented by gracile and cuneate tubercles
- (b) *Superolaterally* by the superior cerebellar peduncle.

### Roof (posterior wall)

The roof of the 4th ventricle is tent-shaped and has upper and lower sloping surfaces. The apex of the tent extends posteriorly into the white core of the cerebellum.

The *upper part of the roof* is formed by a thin sheet of white matter, the **superior medullary velum** that stretches between the two superior cerebellar peduncles.

The *lower part of the roof* is formed by a thin sheet of non-nervous tissue, the **inferior medullary velum** that is formed conjointly by the ventricular ependyma and the pia mater.

The lower part of the roof is perforated by a *midline slit*, the **median aperture** (the **foramen of Magendie**) through which the cavity of the 4th ventricle communicates with the subarachnoid space of the *cerebellomedullary cistern (cisterna magna)*.

The cavity of the 4th ventricle is prolonged laterally as a narrow *lateral recess* behind and around the inferior cerebellar peduncle which opens as *lateral aperture* (foramen of Luschka) into the subarachnoid space in the region of cerebellopontine angle.

Through these three apertures in the lower part of the roof of the 4th ventricle, CSF escapes from the ventricular system into the subarachnoid space for absorption by the arachnoid villi and granulations.

### **Choroid plexuses of the fourth ventricle**

The choroid plexus is a tuft of capillaries that project into the cavity of the 4th ventricle through the lower part of its roof. It receives its blood supply from a branch of posterior inferior cerebellar artery. The entire plexus is ‘T-shaped’, where the vertical limb of ‘T’ is double with foramen of Magendie intervening between the two limbs. The horizontal limb of plexus on either side extends into the lateral recess and protrudes through the lateral aperture, the **foramen of Luschka** into the subarachnoid space, and can be seen on the inferior surface of the brain, near the flocculus of the cerebellum.

### **Floor (rhomboid fossa)**

The floor of the 4th ventricle is formed by the posterior surface of the pons and the upper part of the medulla.

It is rhomboid in shape (diamond shaped) and because of its shape; the floor of the 4th ventricle is often called **rhomboid fossa** ([Fig. 25.5](#)). It is divisible into two parts.

**FIG. 25.5** ■ Rhomboid fossa (floor of the 4th ventricle).  
C, cuneate tubercle; G, gracile tubercle.

The upper triangular part is bounded on each side by the superior cerebellar peduncle, whereas the lower triangular part is bounded on each side by gracile and cuneate tubercles and the inferior cerebellar peduncle.

### Features of the floor of the fourth ventricle (rhomboid fossa)

The floor of the 4th ventricle exhibits the following features:

1. The entire floor is divided into right and left symmetrical halves by a **median sulcus**, which extends from the aperture of the aqueduct of the midbrain above to the commencement of the central canal below.
2. At its widest part, the floor is crossed transversely by glistening white fibres, the **stria medullaris**. These fibres are derived from arcuate nuclei, which emerge from the median sulcus and run transversely across the floor to enter into the inferior cerebellar peduncle.
3. On either side of the median sulcus, there is a longitudinal elevation called **medial eminence**.

4. The medial eminence is bounded laterally by **sulcus limitans** .
5. At the lateral angle of the floor, the region lateral to sulcus limitans overlies the vestibular nuclei and hence it is termed the **vestibular area** .
6. The upper end of sulcus limitans widens into a triangular depression called **superior fovea** . Above the superior fovea, the sulcus limitans flattens out and presents a bluish grey area called **locus coeruleus** . The colour is imparted by the underlying group of nerve cells containing melanin pigment which constitute the **substantia ferruginea** .
7. The lowermost part of sulcus limitans presents a small depression called **inferior fovea** .
8. On either side, the medial eminence presents an oval swelling in the pontine part of floor at the level of superior fovea, the **facial colliculus** . The swelling is produced by the fibres from the motor nucleus of facial nerve hooking around the abducent nucleus (**internal genu of the facial nerve** ).
9. From inferior fovea, the sulcus limitans descends obliquely towards the median sulcus. This sulcus divides the medial eminence in the medullary part of the floor into two triangles: the hypoglossal triangle above and the vagal triangle below.
10. The **hypoglossal triangle** is divided by a faint oblique furrow into a medial part overlying the *nucleus of the hypoglossal nerve* and a lateral part overlying the *nucleus intercalatus*.
11. The **vagal triangle** overlies the nuclei of vagus, glossopharyngeal, and cranial accessory nerves.
12. The **vagal triangle** is crossed by a narrow translucent ridge called **funiculus separans** . A small area between the funiculus separans above and the gracile tubercle below is called **area postrema** .
13. The inferolateral margins of the 4th ventricle are marked by a narrow white ridge called **taenia** . The two taeniae meet at the inferior angle of the ventricle to form a small fold called **obex** . The obex forms the roof of the inferior angle of the 4th ventricle. The term obex is often used to denote the inferior angle of the 4th ventricle.

## CLINICAL CORRELATION

**Tumours of the 4th ventricle:** The tumours in the region of the 4th ventricle are not uncommon. The tumours of 4th ventricle are *ependymoma*

and *medulloblastoma* . The most common tumour in this region is *medulloblastoma* . It arises from the poorly differentiated primitive neuroectodermal cells of cerebellar vermis and occurs mostly in children.

The *medulloblastoma* is highly malignant and produces the signs and symptoms of cerebellar lesions. It may press upon the vital centres located beneath the floor of the ventricle causing cardiac irregularities, tachycardia, irregular respiration, and vasomotor disturbances.

The *ependymoma* arises from proliferation of ependymal cells. It may cause obstruction to the flow of CSF which may lead to the formation of *internal hydrocephalus* .

### Golden Facts to Remember

• <b>Oldest part (phylogenetically) of the cerebellum</b>	Archicerebellum
• <b>Most recent part (phylogenetically) of the cerebellum</b>	Neocerebellum
• <b>Largest cerebellar peduncle</b>	Middle cerebellar peduncle
• <b>Largest and the most prominent intracerebellar nucleus</b>	Dentate nucleus
• <b>All the afferent fibres of the cerebellum are mossy fibres except</b>	Olivocerebellar and parolivocerebellar fibres which are <i>climbing fibres</i>
• <b>All intrinsic neurons of the cerebellar cortex are inhibitory except</b>	Granule cells
• <b>Most conspicuous fissure of the cerebellum</b>	Horizontal fissure
• <b>Arbor vitae cerebelli</b>	Central core of white matter of the cerebellum arranged in the form of the branching pattern of a tree
• <b>Parts of the cerebellum liable to herniate through the foramen magnum</b>	Tonsils

## CLINICAL CASE STUDY

A 45-year-old person visited his family physician and complained that he noticed clumsiness in his right hand. The symptoms had started 3 months back but now they were getting worse day by day. He also noticed tremors when he wrote, which disappeared as he stopped writing. He also told that he tends to sway towards the right side while walking. He was referred to a neurologist who on examination found hypotonia of muscles on the right side. When asked to walk along a straight line on the floor, he swayed over to the right side and when he was asked to touch the tip of his nose with his right index finger, the finger started tremoring as it was nearing the nose and overshot the target. When he was asked to perform rapidly, alternating opposite movements (e.g., supination and pronation), he could not do so by his right hand. The MRI of skull revealed a large **tumour in his right cerebellar hemisphere**.

### Questions

1. What are the three parts of the cerebellum?
2. What are the main functions of the cerebellum?
3. Enumerate the three morphological subdivisions of the cerebellum and mention the primary function of each subdivision.

### Answers

1. Two cerebellar hemispheres and a vermis.
2. The main functions of the cerebellum are the maintenance of equilibrium and posture, the regulation of muscle tone, and the coordination of somatic motor activities.
3. The three morphological subdivisions of the cerebellum are archicerebellum, paleocerebellum, and neocerebellum.  
The maintenance of equilibrium is the primary function of the *archicerebellum*, the regulation of muscle tone and posture of trunk and limbs is the primary function of the *paleocerebellum*, and the smooth performance of fine voluntary movements is the primary function of the *neocerebellum*.

---

# Chapter 26: Diencephalon and third ventricle

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe the boundaries, parts, gross relations, major nuclei, and connections of dorsal thalamus, hypothalamus, epithalamus, and metathalamus. **AN 62.5**
- Tell the subdivisions of diencephalon and describe thalamus (dorsal thalamus) in detail.
- Describe hypothalamus in brief under the following headings: (a) boundaries, (b) regions and nuclei, (c) functions, and (e) applied anatomy.
- Describe the third ventricle under the following headings: (a) boundaries, (b) features, (c) recesses, and (d) applied anatomy. **AN 63.1**

## Diencephalon

The diencephalon is a part of brain situated cranial to the midbrain and is more or less completely surrounded by the cerebrum. The cavity within the diencephalon is termed the **3rd ventricle**. It communicates on either side with the lateral ventricle of the cerebral hemisphere.

The cavity of the 3rd ventricle divides the diencephalon into two (right and left) symmetrical halves.

## Divisions and subdivisions

The diencephalon is divided into two major parts: **pars dorsalis** and **pars ventralis**. These subdivisions are seen in mid-sagittal view of the brain and

are separated from each other by a shallow groove, the *hypothalamic sulcus*, which extends from interventricular foramen to the rostral end of the cerebral aqueduct of the midbrain (see [Fig. 26.4](#) ).

- Pars dorsalis** lies above (dorsal) the **hypothalamic sulcus** and consists of: (1) thalamus, (2) metathalamus, and (3) epithalamus.
- Pars ventralis** lies below (ventral) the **hypothalamic sulcus** and consists of: (1) subthalamus and (2) hypothalamus.

Thus, the diencephalon is divided into five parts: thalamus, metathalamus, epithalamus, subthalamus, and hypothalamus. Each of these parts has further subdivisions.

The main divisions and subdivisions of the diencephalon are listed in [Table 26.1](#) .

 **TABLE 26.1**

**Divisions and subdivisions of the diencephalon**

Divisions	Subdivisions
<b>Pars dorsalis</b>	
• Thalamus (dorsal thalamus)	
• Metathalamus	Medial and lateral geniculate bodies
• Epithalamus	Pineal gland, habenular nuclei and commissure and posterior commissure
<b>Pars ventralis</b>	
• Subthalamus (ventral thalamus)	Subthalamic nucleus and zona incerta
• Hypothalamus	

**Thalamus AN 62.5**

Anatomically, thalamus is a large ovoid mass of grey matter lying above the midbrain, from which it is separated by a small amount of neural tissue, the **subthalamus** . There are two thalami situated one on each side of a slit-like cavity, the **3rd ventricle** ([Fig. 26.1](#) ).

**FIG. 26.1** ■ The thalami and 3rd ventricle as seen from above, after removing the overlying tela choroidea.

Each thalamus is 3.5 to 4 cm in length and 1.5 cm in breadth.

The long axes of the thalami are set obliquely, running backward and laterally. The pointed anterior ends are nearer to the median plane, whereas the wider posterior ends are separated from each other by pineal body, superior colliculi, and habenular triangles. The thalami are usually attached across the median plane by a narrow **interthalamic connexus** of grey matter (also called **interthalamic adhesion**). Each thalamus forms most of the lateral wall of the 3rd ventricle and floor of the central part of the lateral ventricle.

*Functionally, thalamus is considered as the great sensory gateway to the cerebral cortex.* It receives impulses from opposite half of the body and transmits most of them to the sensory area of the cerebral cortex (Brodmann areas 3, 2, and 1).

### External features

Each thalamus has **two ends** and **four surfaces**.

## Ends

### Anterior end

The anterior end is narrow and constitutes the **tubercle of thalamus** . It forms the posterior boundary of the interventricular foramen.

### Posterior end

The posterior end is expanded and is known as **pulvinar** . It overhangs the medial and lateral geniculate bodies and superior colliculi with their brachia.

## Surfaces

### Superior surface

Its lateral part forms the floor of the central part of the lateral ventricle and its medial part is covered by the tela choroidea of the 3rd ventricle and fornix.

### Inferior surface

Its anterior part is fused with the subthalamus while its posterior part is free, forming the inferior aspect of the pulvinar.

### Medial surface

It forms the greater part of the lateral wall of the 3rd ventricle.

### Lateral surface

It forms the medial boundary of the posterior limb of the internal capsule.

## Parts of the thalamus

The thalamus is traversed anteroposteriorly by a vertical sheet of white fibres, **internal medullary lamina** which bifurcates anteriorly to assume a Y-shaped configuration. This Y-shaped internal medullary lamina divides the thalamus into three main parts: anterior, medial, and lateral.

The **anterior part** includes the anterior tubercle and lies between the 'limbs' of the 'Y'. The **medial and lateral parts** lie on either side of the 'stem' of the 'Y'. Each of these parts consists of a number of nuclei.

## Nuclei of the thalamus (Fig. 26.2 )

**FIG. 26.2 ■** Horizontal section of the thalamus (schematic) to show the location of various thalamic nuclei. LD, lateral dorsal nucleus; LP, lateral posterior nucleus; P, pulvinar; VA, ventral anterior nucleus; VL, ventral lateral nucleus; VPL, ventral posterolateral nucleus. The VPM (ventral posteromedial nucleus) is not visible in the diagram.

### Nuclei in the anterior part

The nuclei in this part are collectively referred to as **anterior nucleus** .

### Nuclei in the medial part

Nuclei in medial part consist of a large **medial dorsal nucleus** and a small **medial ventral nucleus** .

### Nuclei in the lateral part

The lateral part is divided into dorsal and ventral parts.

The dorsal part is subdivided craniocaudally into three nuclei: (1) *lateral dorsal* (LD), (2) *lateral posterior* (LP), and (3) a large caudal nuclear mass, the *pulvinar* (P). These nuclei are termed **dorsal tier of nuclei** .

The ventral part is also subdivided craniocaudally into three nuclei: (1) *ventral anterior* (VA), (2) *ventral lateral* (VL) or *ventral intermediate* (VI), and (c) *ventral posterior* (VP). These nuclei are termed **ventral tier of nuclei**.

The *ventral posterior nucleus* (VP) is further subdivided into a lateral part, the *ventral posterolateral nucleus* (VPL) and a medial part, the *ventral posteromedial nucleus* (VPM).

The thalamic nuclei are summarized in [Table 26.2](#).

 **TABLE 26.2**

### Nuclei in different parts of the thalamus

Part	Nuclei
Anterior part	Anterior nucleus
Medial part	Medial dorsal nucleus, medial ventral nucleus
Lateral part	
• Dorsal tier nuclei	Lateral dorsal, lateral posterior, pulvinar
• Ventral tier nuclei	Ventral anterior (VA), ventral lateral (VL), ventral posterior: (1) ventral posterolateral (VPL), (2) ventral posteromedial (VPM)

### Connections of the thalamic nuclei

The important connections of thalamic nuclei are as follows:

From a clinical point of view, the connections of ventral posterior nucleus are most important because its smaller medial portion, the **VPM** receives general sensory modalities from the head and face through *trigeminal lemniscus* and tastes sensations from taste buds through *solitario thalamic tract*; and its larger lateral portion, the **VPL** receives exteroceptive sensations (pain, touch, temperature) through *spinal lemniscus* and proprioceptive sensations (muscle and joint sense, vibration, two-point discrimination) through *medial lemniscus*, from the rest of the body except face and head.

All the sensations reaching the ventral posterior nucleus are carried to primary sensory area of the cerebral cortex by fibres passing through the posterior limb of the internal capsule (**superior thalamic radiation**). The vascular lesions involve posterior limb of the internal capsule which sometimes cause impairment of all forms of sensibility on the opposite side of the body.

The integrity of **anterior nucleus** and its connections is necessary for attention and recent memory; therefore, a lesion involving it can lead to **loss of recent memory**.

Because the **medial dorsal nucleus** is associated with '*moods*' and *emotional balance*, depending on the nature of the present sensory input and past experience, the mood may be that of well-being or malaise, or of euphoria or mild depression.

## Functions of the thalamus

The main functions of the thalamus are as follows:

1. It is a sensory integration and relay station of all the sensory pathways except for the olfactory pathway which is projected directly to the cerebral cortex without being relayed in the thalamus.
2. It is capable of recognition, though poorly, of pain, thermal and some tactile sensations at its own level.

## CLINICAL CORRELATION

**Thalamic syndrome:** It usually occurs subsequent to a vascular lesion of the thalamus, when the patient is recovering from a thalamic infarct.

### Characteristic features

In thalamic syndrome, the threshold for pain, touch, and temperature is decreased on the opposite side of the body (*thalamic overreaction*), but when the threshold is reached, the sensations are exaggerated, perverted, and disagreeable. For example, the prick of a pin may be felt as a severe burning sensation and music that is ordinarily pleasing may be disagreeable. Sometimes even light touch may produce excruciating pain, which may become intractable and fail to respond to powerful analgesics (pain-relieving) drugs. There may be emotional instability with spontaneous laughing and crying.

## **Metathalamus AN 62.5**

The metathalamus consists of medial and lateral geniculate bodies. These are small, rounded elevations on the inferior aspect of the posterior part of the thalamus, lateral to each side of the midbrain. The medial and lateral geniculate bodies are relay stations for the auditory and visual pathways, respectively.

### **Medial geniculate body**

Medial geniculate body is an oval elevation on the inferior aspect of the pulvinar of the thalamus, lateral to the superior colliculus. It is more prominent than the lateral geniculate body. The inferior brachium runs upward, laterally, and forward from inferior colliculus of the midbrain to the medial geniculate body.

The inferior brachium conveys auditory impulses to the medial geniculate body for onward transmission to the (primary auditory area of the) cerebral cortex.

### **Lateral geniculate body**

Lateral geniculate body is a small ovoid prominence visible at the terminal end of the optic tract. It is situated on the inferior surface of the pulvinar, anterolateral to the medial geniculate body. It is smaller than the medial geniculate body and connected to the superior colliculus by the superior brachium.

The fibres of superior brachium are concerned with the production of visual reflexes such as turning of head and eyes towards the sudden flash of light and constriction of pupil when light falls or is thrown on the pupil of eyes.

The lateral geniculate body receives retinal fibres of both the eyes (from temporal half of the retina of the same side and nasal half of the retina of the opposite side) through optic tract and gives rise to fibres of the *optic radiation* which convey visual impulses to the visual cortex of the occipital lobe.

## **Epithalamus AN 62.5**

### **Pineal gland (epiphysis cerebri)**

Pineal gland is a midline cone-shaped reddish grey structure (only 3 mm × 5 mm in size) occupying the vertical groove between two superior colliculi

below the splenium of corpus callosum. It projects back from the posterior wall of the 3rd ventricle, below the splenium of the corpus callosum. It has a stalk which divides into two laminae. The ventral (or inferior) lamina continues with the **posterior commissure** and the dorsal (or superior) lamina continues with the **habenular commissure**. The extension of the cavity of the 3rd ventricle between the two laminae is termed **pineal recess**.

### Structure and functions

The pineal gland is a **neuroendocrine gland** and consists of parenchymal cells, called *pinealocytes* and neuroglial cells. The pinealocytes secrete a hormone called **melatonin**. The calcium phosphates and carbonates are deposited in the gland with age in the form of multilaminar corpuscles called **corpora arenacea** or **brain sand**. They are often seen as tiny shadows in radiographs of the skull. A displaced calcified pineal gland indicates a space-occupying lesion within the brain.

Pineal secretions including melatonin have an **inhibitory effect** on other endocrine glands and gonads.

### Unique features

Pineal gland is part of the brain which consists of portions of neurons and specialized neuroglial cells called pinealocytes.

It is the only part of the brain which is supplied by a nerve (*nervus conarii*) which arises from outside the brain from superior cervical sympathetic ganglion in the neck.

### Subthalamus AN 62.5

Subthalamus is described in detail on page 389.

### Hypothalamus AN 62.5

The hypothalamus is a part of the diencephalon which lies below the thalamus. It forms the floor and the lower parts of lateral walls of the 3rd ventricle. Anatomically, hypothalamus is small in size weighing only 4 g and forming only 0.3% of the total brain mass, but physiologically there is hardly any activity in the body that is not influenced by it. Thus, the functional significance of hypothalamus is disproportionate to its size. The hypothalamus controls the autonomic and endocrine systems at the highest level, and is also involved in some affective or emotional behaviour. *Being the*

*principal autonomic centre of the brain, it has been regarded as the **head ganglion of the autonomic nervous system** by Sherrington.*

### **Boundaries of the hypothalamus**

The boundaries of the hypothalamus are as follows:

*Anteriorly:* Lamina terminalis (lamina terminalis extends from the optic chiasma to the anterior commissure).

*Posteriorly:* Subthalamus and mesencephalic tegmentum.

*Inferiorly:* Structures in the floor of the 3rd ventricle, namely tuber cinereum, infundibulum, and mammillary bodies. (These structures are actually the parts of hypothalamus itself.)

*Superiorly:* Thalamus.

*Laterally:* Internal capsule.

*Medially:* Cavity of the 3rd ventricle.

### **Subdivisions of the hypothalamus**

The hypothalamus is also subdivided anteroposteriorly into the following four regions:

1. **Preoptic region** – adjoining the lamina terminalis.
2. **Supraoptic region** – above the optic chiasma.
3. **Tuberal region** – includes the tuber cinereum, infundibulum and area around it.
4. **Mammillary region** – includes the mammillary bodies and area around it.

The *preoptic region* lies anterior to the hypothalamus between the optic chiasma and anterior commissure. Anatomically, it belongs to telencephalon but functionally it belongs to hypothalamus.

The *tuber cinereum* is the region bounded caudally by mammillary bodies and rostrally by optic chiasma. The *infundibulum* connects the posterior lobe of the hypophysis cerebri with the tuber cinereum. The tuber cinereum around the base of the infundibulum is raised to form a **median eminence**.

### **Hypothalamic nuclei**

The hypothalamus consists of numerous cell groups called **hypothalamic nuclei**. The nuclei present in different regions of the hypothalamus are listed in [Table 26.3](#) and shown in [Figure 26.3](#).

 **TABLE 26.3**

---

### Hypothalamic regions and nuclei in them

---

Region	Nucleus/nuclei
Preoptic region	<ul style="list-style-type: none"><li>• Preoptic nucleus</li></ul>
Supraoptic region	<ul style="list-style-type: none"><li>• Supraoptic nucleus</li><li>• Anterior nucleus</li><li>• Paraventricular nucleus</li></ul>
Tuberal region	<ul style="list-style-type: none"><li>• Arcuate (infundibular) nucleus</li><li>• Ventromedial nucleus</li><li>• Dorsomedial nucleus</li></ul>
Mammillary region	<ul style="list-style-type: none"><li>• Posterior nucleus</li><li>• Mammillary nuclei</li></ul>

**FIG. 26.3** ■ Different nuclei of the hypothalamus as seen in the sagittal section.

### Connections of the hypothalamus

The connections of the hypothalamus are numerous and complex; therefore, only main connections are described below:

1. The axons of supraoptic and paraventricular nuclei run in the pituitary stalk to reach the posterior pituitary (neurohypophysis) and form the **hypothalamohypophyseal tract**. These axons transport the neurohormones – vasopressin and oxytocin – synthesized in supraoptic nucleus and paraventricular nucleus, respectively, to the posterior pituitary.
2. The axons of other cell groups, for example, tuberal nuclei enter the region of median eminence to deliver their neurosecretory material to the **hypothalamohypophyseal portal system** of blood vessels to control the secretion of hormones from the anterior pituitary (adenohypophysis).

3. The long axons from hypothalamus pass through the brainstem and spinal cord to synapse with the preganglionic sympathetic cells in the lateral horns of the thoracic and upper two lumbar spinal segments and with the preganglionic parasympathetic cells in the lateral horns of the S2, S3, and S4 spinal segments to form hypothalamospinal tract.
4. **Mammillothalamic tract** connects the mammillary body to the anterior nucleus of the thalamus, which in turn projects to the cingulate gyrus.

## Functions of the hypothalamus

1. **Autonomic control:** The anterior part of the hypothalamus controls the parasympathetic nervous system, whereas posterior part controls the sympathetic nervous system.
2. **Endocrine control:** Regulates the hormonal secretion of the anterior pituitary by forming the releasing factors or release inhibiting factors which in turn control the endocrine activities of the body.
3. **Neurosecretion:** Secretes neurohormones – oxytocin and vasopressin.
4. **Regulation of food and water intake:** The lateral part of the hypothalamus acts as **hunger centre**, whereas the medial part acts as **satiety centre**. A **thirst centre** in the lateral part regulates water intake.
5. **Emotional expression:** *Plays an important role in the expression of autonomic emotions* such as laughing, crying, sweating, or blushing mediated by the integrated activity of the ANS and somatic efferent system.
6. **Sexual behaviour and reproduction:** Regulates the sexual behaviour and reproduction by influencing the secretion of gonadotrophic hormones by the pituitary gland.
7. **Temperature regulation:** Anterior portion of the hypothalamus prevents the rise in body temperature, whereas posterior portion promotes heat conservation and heat production.
8. **Biological clock:** Regulates the cyclic activities of the body (*circadian rhythm* ), namely sleeping and waking cycle, but itself affected by diurnal rhythms. The circadian rhythm for many body functions is approximately 24 hours.

## Third ventricle AN 63.1

The 3rd ventricle is the **cavity of diencephalon and lies in the centre of brain** . It is a midline slit-like cavity situated between two thalami and part of hypothalamus. It extends from the lamina terminalis anteriorly to the superior end of the cerebral aqueduct of the midbrain posteriorly. The cavity of the 3rd ventricle is lined by ciliated columnar epithelium, the **ependyma** and traversed horizontally by a mass of grey matter, the **interthalamic adhesion** , connecting the two thalami. The outline of the cavity is irregular because of the presence of several diverticula or recesses.

Anteriorly on each side, the 3rd ventricle communicates with the lateral ventricle through **interventricular foramen (of Monro)** , and posteriorly with the 4th ventricle through *cerebral aqueduct (of Sylvius)*.

## Boundaries AN 63.1

The 3rd ventricle has anterior wall, posterior wall, roof, floor, and two lateral walls ([Fig. 26.4](#) ).

*Anterior wall* is formed from above downward by:

- (a) Anterior column of fornix
- (b) Anterior commissure
- (c) Lamina terminalis

*Posterior wall* is formed from above downward by:

- (a) Pineal gland
- (b) Posterior commissure
- (c) Commencement of cerebral aqueduct

*Roof* is formed by the ependyma that stretches across the upper limits of two thalami

*Floor* is formed from before backward by:

- (a) Optic chiasma
- (b) Tuber cinereum and infundibulum
- (c) Mammillary bodies
- (d) Posterior perforated substance
- (e) Tegmentum of the midbrain.

**FIG. 26.4 ■** Boundaries and recesses of the 3rd ventricle as seen in sagittal section. HS, hypothalamic sulcus; I, interthalamic adhesion; 1, infundibular recess, 2, optic recess; 3, anterior recess; 4, suprapineal recess; 5, pineal recess.

### **N.B.**

All structures of the floor belong to interpeduncular fossa *except* the optic chiasma and tegmentum of the midbrain.

*Lateral wall* is marked by a curved sulcus, the **hypothalamic sulcus** extending from the interventricular foramen to the upper end of the cerebral aqueduct. The sulcus divides the lateral wall into a larger upper part and a smaller lower part.

- The larger **upper part of the lateral wall** is formed by the medial surface of the anterior two-third of the thalamus.
- The smaller **lower part of the lateral wall** is formed by the

hypothalamus and it is continuous with the ventricular floor.

### N.B.

The two lateral walls of the 3rd ventricle are normally closely approximated; hence, in coronal section of the brain, the cavity of the 3rd ventricle appears as a *median vertical slit* (Fig. 26.1 ).

## Recesses

The cavity of the 3rd ventricle extends into the surrounding structures as pocket-like protrusions called recesses (Fig. 26.4 ). These are as follows:

1. **Infundibular recess:** It is a deep tunnel-shaped recess extending downward through the tuber cinereum into the infundibulum, i.e., the stalk of the pituitary gland.
2. **Optic (or chiasmatic) recess:** It is an angular recess situated at the junction of the anterior wall and the floor of the ventricle just above the optic chiasma.
3. **Anterior recess (vulva of the ventricle):** It is a triangular recess which extends anteriorly in front of interventricular foramen and behind anterior commissure between the diverging anterior columns of the fornix.
4. **Suprapineal recess:** It is a fairly capacious blind diverticulum, which extends posteriorly above the stalk of the pineal gland and below the tela choroidea.
5. **Pineal recess:** It is a small diverticulum which extends posteriorly between the superior and inferior laminae of the stalk of the pineal gland.

## Choroid plexus and tela choroidea

The tela choroidea in the roof of the 3rd ventricle is triangular in shape. The choroid plexus of the 3rd ventricle hangs downward from the tela choroidea as two longitudinal anteroposterior vascular fringes.

### CLINICAL CORRELATION

**Obstruction of 3rd ventricle:** The 3rd ventricle being a narrow slit-like space is easily obstructed by local brain tumours or congenital defects. The obstruction results in excessive accumulation of CSF inside the brain, resulting in an *increased intracranial pressure* in adults and in

*hydrocephalus* in children.

The site of obstruction can be found out by *ventriculography* .

### **Golden Facts to Remember**

• <b>Great sensory gateway to the cerebral cortex</b>	Thalamus
• <b>Largest somatosensory relay nucleus of the thalamus</b>	Ventral posterior nucleus
• <b>Thalamus is the final relay station of all the sensory modalities except</b>	Olfaction
• <b>Only part of the brain which is supplied by a nerve arising from outside the brain</b>	Pineal gland (supplied by nervus conarii, which carries sympathetic fibres from superior cervical sympathetic ganglion)
• <b>Head ganglion of the autonomic nervous system</b>	Hypothalamus
• <b>Anatomically, all the regions of hypothalamus belong to the diencephalon except</b>	Preoptic region which belongs to telencephalon

### **CLINICAL CASE STUDY**

A 55-year-old patient was admitted in the neurology ward with complaints of loss of sensation on the left side of his body. After a few days, the patient started improving and there was an evidence of return of sensations on the affected side. Both, the treating doctors and relatives were very happy. Few days later, he suddenly started complaining of agonizing pain in his left arm and leg. The pain would start spontaneously or may be initiated by the light touch of even bedsheet or by little exposure to the cold. The pain failed to respond even to powerful analgesics. He was diagnosed as a case of **thalamic syndrome** .

### **Questions**

1. What is thalamus? What is its main function?

2. Enumerate the ventral tier of the thalamic nuclei.
3. Name the nucleus of thalamus concerned with the general sensations of pain, touch, and temperature from opposite half of the body.
4. What is thalamic syndrome?

## Answers

1. The thalamus is a large ovoid mass of grey matter lying above the brainstem from which it is separated by a small amount of neutral tissue – the *subthalamus*. The main function of thalamus is that it is a great sensory relay station in which all the sensory pathways relay *except* olfactory.
2. The ventral tier of thalamic nuclei include ventral anterior (VA), ventral lateral (VL) or ventral intermediate (VI), and ventral posterior (VP). The ventral posterior nucleus is further divided into ventral posterolateral (VPL) and ventral posteromedial (VPM) nuclei.
3. Ventral posterolateral (VPL) nucleus.
4. The thalamic syndrome is thalamic overreaction to the sensations of pain, touch, and temperature. It occurs when the patient is recovering from thalamic infarct following a vascular lesion of the thalamus.

---

# Chapter 27: Cerebrum

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Describe surfaces, sulci, gyri, poles, and functional areas of cerebral hemisphere. **AN 62.2**
- Draw the labelled diagrams to show: (a) functional cortical areas on the superolateral surface of cerebral hemisphere, (b) parts of lateral ventricle, (c) parts of corpus callosum, and (d) types of fibres in corpus callosum.
- Write short notes on: (a) circle of Willis, (b) great cerebral vein of Galen, (c) motor speech area, and (d) cerebral dominance.
- Describe the white matter of cerebrum. **AN 62.3**
- Describe the internal capsule under the following headings: (a) shape and parts, (b) constituent fibres, (c) arterial supply, and (d) applied anatomy.
- Describe the parts, boundaries, and features of lateral ventricle. **AN 63.1**

The cerebrum (Latin = *brain* ) is the largest part of the brain that fills most of the cranial cavity above the floors of anterior and middle cranial fossae and above the tentorium cerebelli of posterior cranial fossa.

The cerebrum is a heavily convoluted bilobed structure.

A deep median cleft, the **longitudinal cerebral fissure** , incompletely separates the cerebrum into two lateral halves, called **cerebral hemispheres** . The cleft lodges a sickle-shaped fold of the dura mater, the *falx cerebri* and the anterior cerebral vessels. Both in front and behind, the cleft is complete, but in the central part it extends downwards up to the *corpus callosum* which is a large mass of white fibres joining the two cerebral

hemispheres across the median plane.

The left hemisphere in right-handed individuals is slightly larger than the right, and usually called **dominant hemisphere** .

Each cerebral hemisphere consists of: (1) an outer layer of grey matter called **cerebral cortex** , (2) an inner mass of **white matter** , (3) large masses of grey matter embedded in the basal part of the white matter called **basal ganglia/basal nuclei**, and (4) a cavity within it called **lateral ventricle** .

## External features of the cerebral hemisphere AN 62.2

The external features of the cerebral hemisphere include: poles, surfaces, borders, sulci, and gyri.

### Poles

Each cerebral hemisphere presents the following three poles:

1. The **frontal pole** , the anterior end of the hemisphere is more rounded than the occipital pole.
2. The **occipital pole** , the posterior end of the hemisphere is more pointed than the frontal pole.
3. The **temporal pole** between frontal and temporal poles points forwards. It fits into the anterior part of the middle cranial fossa.

### Surfaces

Each cerebral hemisphere has the following three surfaces:

1. The **superolateral surface** is most convex and most extensive. It faces upwards and laterally and conforms to the corresponding half of the cranial vault.
2. The **medial surface** is flat and vertical. It presents a thick C-shaped cut surface of the *corpus callosum*.
3. The **inferior surface** is irregular to adapt to the floors of anterior and middle cranial fossae. It is divided into two parts by a deep horizontal groove or sulcus, the **stem of lateral sulcus** , namely (1) a small anterior part, the *orbital surface*, and (2) a large posterior part, the *tentorial surface*.

### Borders

Each cerebral hemisphere presents the following six borders:

1. The **superomedial border** separates the superolateral surface from the medial surface.
2. The **superciliary border** is at the junction of superolateral and orbital surfaces.
3. The **inferolateral border** separates the superolateral surface from the tentorial surface.
4. The **medial orbital border** separates the medial surface from the orbital surface.
5. The **inferomedial/hippocampal border** surrounds the cerebral peduncle.
6. The **medial occipital border** separates the medial surface from the tentorial surface.

## Sulci and gyri

The cerebral cortex is thrown into a complicated series of tortuous folds, called **gyri or convolutions**. The grooves between the gyri are termed as sulci. The convolutions greatly increase the surface area of the cerebral cortex. Most of the gyri and sulci are named but only important ones are described here.

Each gyrus consists of a central core of white matter covered by an outer layer of grey matter.

## Main cerebral sulci

Main cerebral sulci are fairly constant in position and shape and include lateral, central, calcarine, and parieto-occipital sulci.

**Lateral sulcus (of Sylvius)** is the most conspicuous of all the cerebral sulci and has a **stem** and **three rami**. The stem of the sulcus begins as a deep cleft on the inferior surface of the cerebral hemisphere at the anterior perforated substance and extends laterally to reach the superolateral surface. On reaching the superolateral surface, it divides into three rami: (1) *anterior horizontal*, (2) *anterior ascending*, and (3) *posterior*.

## N.B.

The three rami of lateral sulcus diverge from each other at a point called **Sylvian point**.

**Central sulcus (of Rolando)** begins by cutting the superomedial border of the hemisphere approximately 1 cm behind the midpoint between the frontal and occipital poles, runs sinuously downwards and forwards, and ends just above the posterior ramus of the lateral sulcus. Its upper end usually extends into the medial surface.

**Calcarine sulcus** is present on the medial surface of the cerebral hemisphere. It begins as a deep fissure, a little below the posterior end of the corpus callosum, the splenium, and follows an arched course with a convexity upwards to the occipital pole and may extend slightly onto the superolateral surface.

**Parieto-occipital sulcus** is present on the medial surface of the hemisphere. It begins at the midpoint of the calcarine sulcus and courses upwards and slightly backwards to cut the superomedial border of the hemisphere approximately 5 cm in front of the occipital pole, and may extend slightly onto the superolateral surface.

## **Sulci and gyri on superolateral surface**

### ***In the frontal lobe***

1. The **precentral sulcus**, often broken into two or three parts, runs downwards and forwards parallel and little anterior to the central sulcus. The area between the central and precentral sulci is called **precentral gyrus**.
2. Anterior to the precentral sulcus, there are two sulci called **superior** and **inferior frontal sulci** which run horizontally. These sulci divide the region of frontal lobe in front of precentral sulcus into **superior**, **middle**, and **inferior frontal gyri**.
3. The **anterior** and **ascending rami of lateral sulcus** divide the inferior frontal gyrus into three parts. The part below the anterior ramus is called *pars orbitalis*, the part between the anterior and ascending rami is *pars triangularis*, and the part posterior to the ascending ramus, the *pars opercularis*.

### ***In the parietal lobe***

1. The **postcentral sulcus** runs downwards and forwards, a little behind and parallel to the central sulcus. The area between these two sulci is called *postcentral gyrus*.
2. The rest of the parietal lobe is divided into **superior** and **inferior parietal lobules** by an *intraparietal sulcus*.

### ***In the temporal lobe***

- There are two sulci in this lobe that run parallel to the posterior ramus of the lateral sulcus. These are termed **superior** and **inferior temporal sulci**, and divide the temporal lobe into **superior, middle, and inferior temporal gyri**.
- The superior surface of superior temporal gyrus presents *two transverse temporal gyri*. The anterior transverse temporal gyrus also called **Heschl's gyrus** forms primary auditory area of the cortex.

### ***In the occipital lobe***

- The occipital lobe possesses rather three short sulci, lateral, and transverse occipital sulci and lunate sulcus.

## **Sulci and gyri on medial surface**

These are as follows:

1. **Cingulate sulcus** : It is the most prominent sulcus which follows a curved course approximately 1 cm above and parallel to the upper convex margin of corpus callosum. Anteriorly, it ends below the genu of corpus callosum; posteriorly, it turns upwards to reach the superomedial border of the hemisphere, a little behind the upper end of the central sulcus.
  - The area between the cingulate sulcus and corpus callosum is termed **cingulate gyrus**.
2. **Callosal sulcus** : It separates the cingulate gyrus from corpus callosum.
  - (a) Anterior part of medial surface between cingulate sulcus and superomedial border of the hemisphere is divided by a short offshoot sulcus ascending from the cingulate sulcus above the middle of the trunk of corpus callosum into two parts:
    - A small part around the upper part of the central sulcus, the *paracentral lobule*
    - A large medial part the *medial frontal gyrus*
  - (b) The posterior part of medial surface behind the paracentral lobule has two main sulci: the calcarine sulcus and the parieto-occipital sulcus.
    - *Calcarine sulcus* (already described). A small region between the splenium and calcarine sulcus is termed **isthmus**.
    - Parieto-occipital sulcus (already described).

- The triangular area between the posterior part of the calcarine sulcus (also called **postcalcarine sulcus** ) and the parieto-occipital sulcus is called *cuneus*.
  - The quadrangular area between the parieto-occipital sulcus and paracentral lobule is termed *precuneus*.
3. A small sulcus a little above and parallel to the splenium is called **suprasplenial sulcus** . It separates the precuneus from the cingulate gyrus.

## **Sulci and gyri on inferior surface**

### ***On the orbital part of inferior surface (orbital surface)***

1. **Olfactory sulcus:** It is a straight sulcus which runs anteroposteriorly close to the medial border of the orbital surface. It is called olfactory sulcus because it lodges the olfactory bulb and tract.

The area medial to this sulcus is called **gyrus rectus** .

2. **Orbital sulcus:** It is an irregular H-shaped sulcus and divides the rest of the orbital surface into **anterior**, **posterior** , medial, and **lateral orbital gyri** .

### ***On the tentorial part of inferior surface (tentorial surface)***

1. The tentorial surface is marked by two major sulci that run anteroposteriorly. The medial one is called **collateral sulcus** and the lateral one, the **occipitotemporal sulcus** .
2. Posteriorly, the collateral sulcus is parallel to the calcarine sulcus and here the area between these two sulci is termed *lingual gyrus*. Anteriorly, the lingual gyrus is continuous with the **parahippocampal gyrus** . Anterior end of parahippocampal gyrus hooks sharply backwards and is limited laterally by a short *rhinal sulcus*. This hook-like anterior end of parahippocampal gyrus is called **uncus** .

Posteriorly, the parahippocampal gyrus is continuous with the cingulate gyrus through the isthmus.

The area between the *occipitotemporal sulcus* laterally and the *collateral* and *rhinal* sulci medially is known as **medial occipitotemporal gyrus** . The area lateral to the occipitotemporal sulcus is termed **lateral occipitotemporal gyrus** . This gyrus is continued around the inferolateral margin of the hemisphere with the inferior temporal gyrus.

## Lobes of cerebral hemisphere

The superolateral surface of each cerebral hemisphere is arbitrarily divided into four lobes, namely, frontal, parietal, temporal, and occipital with the help of: (a) three main sulci: central, lateral, and parieto-occipital, and (b) two imaginary lines (Fig. 23.2 ).

The *first imaginary line* is a vertical line joining the parieto-occipital sulcus to the preoccipital notch, and the second *imaginary line* is a backward continuation of the horizontal part of the posterior ramus of the lateral sulcus till it joins the first line.

The **frontal lobe** lies anterior to the central sulcus and above the posterior ramus of the lateral sulcus.

The **parietal lobe** lies behind the central sulcus and in front of the upper part of the first imaginary line. Below it is bounded by the posterior ramus of the lateral sulcus and the second imaginary line.

The **temporal lobe** lies below the posterior ramus of lateral sulcus and second imaginary line. It is separated from the **occipital lobe** by lower part of the first imaginary line.

The **occipital lobe** lies behind the **vertical** line joining the parieto-occipital sulcus and preoccipital notch.

## Insula/Island of Reil (also called central lobe)

It is customary to consider the insula separately from four main lobes (vide supra) of the cerebral hemisphere.

The insula is the submerged (hidden) portion of the cerebral cortex in the floor of lateral sulcus. It has been submerged from the surface during development of brain because of the overgrowth of the surrounding cortical areas and can be seen only when the lips of the lateral sulcus are widely pulled apart. It is triangular in shape and surrounded all around by a sulcus, the **circular sulcus** , except anteroinferiorly at its apex called **limen insulae** which is continued with the anterior perforated substance.

The insula is divided into two regions, anterior and posterior by a **central sulcus** . The anterior region presents three or four short gyri called **gyri brevia** and the posterior region presents one or two long gyri called **gyri longa** .

The insula is hidden from the surface view by the overgrown cortical areas of frontal, parietal, and temporal lobes. These areas are termed **frontal, frontoparietal, and temporal opercula** (operculum = lid). The superior surface of the temporal operculum presents the **anterior and posterior**

**transverse temporal gyri .**

## **Cerebral cortex**

The cerebral cortex is the surface layer of grey matter covering the cerebral hemisphere. The cortex represents the highest degree of evolutionary development of the human brain both in its relative size to other parts of the brain and its range of functions.

The main functions of the cerebral cortex include:

1. **Mental activities** involved in memory, learning, speech, language, intelligence, and creative thinking.
2. **Sensory perceptions** such as perception of pain, touch, temperature, sight, hearing, taste, and smell.
3. **Initiation of motor commands** to control activities of skeletal muscles.

### **N.B.**

In general, each cerebral hemisphere controls the opposite half of the body, i.e., it sends motor commands to and receives sensory information from the contralateral half of the body.

## **Functional areas**

The surface of cerebral cortex was demarcated by Brodmann (1909) into 47 areas according to their function.

**Types of cortical areas:** according to classical teaching, the cerebral cortex possesses three types of functional areas:

1. **Motor areas:** primarily concerned with the motor functions.
2. **Sensory areas:** primarily concerned with the sensory functions.
3. **Association areas:** not concerned with primary motor or sensory functions but have more important associative, integrative, and cognitive functions.

### **N.B.**

Association areas occupy over 75% of the total surface area of the cerebral cortex in human beings.

## **Functional areas in frontal lobe (Figs 27.1 and 27.2 )**

## Primary motor area (area 4 of Brodmann)

Primary motor area is located in the precentral gyrus on superolateral surface and extends to anterior part of paracentral lobule on medial surface of the cerebral hemisphere. *Approximately 40% pyramidal (corticospinal and corticonuclear) fibres arise from this area.*

**FIG. 27.1 ■** Functional cortical areas (of Brodmann) on the superolateral surface of the cerebral hemisphere.

**FIG. 27.2 ■** Functional cortical areas on the inferomedial surface of the cerebral hemisphere.

Specific regions within the area are responsible for movements in the specific parts of the body. Only movements are represented in this area and not the muscles.

In the motor area of the cerebrum, the human body is represented upside down, that is, uppermost part controls the feet, and the lowermost part controls the head, neck, face, and fingers.

### CLINICAL CORRELATION

**Lesions of primary motor area** in one hemisphere produce spastic paralysis of the extremities of the opposite half of the body (*hemiplegia*). The masticatory, laryngeal, pharyngeal, upper facial, and extraocular muscles are spared for being represented bilaterally.

#### Premotor area (area 6 of Brodmann)

Premotor area is located anterior to the primary motor area in the posterior parts of superior, middle, and inferior frontal gyri and extends on to the medial surface of the hemisphere.

The premotor area is responsible for successful performance of the voluntary motor activities initiated in the primary motor area.

### Frontal eye field (area 8 of Brodmann)

The frontal eye field is located in the posterior part of the middle frontal gyrus just anterior to the facial area of the precentral gyrus. It is responsible for **conjugate movements of the eyes** to the opposite side.

### Motor speech area of Broca (areas 44 and 45 of Brodmann)

The motor speech area is usually located in the pars triangularis (area 45) and pars opercularis (area 44) of inferior frontal gyrus of frontal lobe of left hemisphere (the *dominant hemisphere* in right-handed and most of the left-handed individuals).

#### CLINICAL CORRELATION

**Lesions of motor speech area of Broca** result in loss of ability to produce proper speech, called *expressive aphasia* (also called *motor aphasia*). The patients face difficulty in finding the right words to express what they wish to say, but they can understand what others say.

### Primary sensory area (areas 3, 1, and 2 of Brodmann)

Primary sensory area is located in the postcentral gyrus and extends into the posterior part of the paracentral lobule on the medial surface of the hemisphere. The opposite half of the body is represented upside down exactly in same fashion as in the primary motor area. *The primary sensory area is concerned with the perception of exteroceptive (pain, touch, and temperature) and proprioceptive (vibration, muscle, and joint sense) sensations from the opposite half of the body.*

#### CLINICAL CORRELATION

**Lesions of primary sensory area** lead to loss of appreciation of exteroceptive and proprioceptive sensations from the opposite half of the body.

### Sensory association area (Fig. 27.1 )

Sensory association area occupies the superior parietal lobule corresponding to the areas 5 and 7 of Brodmann. *It is concerned with the perception of shape, size, roughness, and texture of the objects.* Thus, it enables the individual to recognize the objects placed in his or her hand without seeing. Such ability is referred to as **stereognosis**.

## Sensory speech area of wernicke (Fig. 27.1 )

Sensory speech area is located in the left dominant hemisphere occupying the posterior part of the superior temporal gyrus of temporal lobe (area 22) and angular (area 39) and supramarginal (area 40) gyri of the inferior parietal lobule.

*The Wernicke's area is concerned with the understanding of speech, i.e., interpretation of spoken and written words.*

### CLINICAL CORRELATION

**Lesions of Wernicke's area in the dominant hemisphere** produce loss of ability to understand the spoken and written speech. This condition is called **receptive aphasia** . In this condition person is unable to understand both written and spoken speech although his vision and hearing are normal.

### N.B.

Recently, it has been found that traditional motor and sensory areas are not exclusively motor or sensory but sensorimotor in nature. The motor areas are predominantly motor, whereas the sensory areas are predominantly sensory, and they are abbreviated as **Ms** and **Sm** , respectively, according to *relative* significance of their functional attributes. Thus, primary somatomotor area is abbreviated as MsI, supplementary motor area as MsII, first somatosensory area as SmI, and second somatosensory area as SmII.

## Functional areas in temporal lobe

### Primary auditory area (areas 41 and 42)

Primary auditory area is located on the superior surface of the superior temporal gyrus occupying the anterior transverse temporal gyrus (**Heschl's gyrus** ) and extends slightly to the adjacent part of the superior temporal gyrus (Fig. 27.1 ).

### Secondary auditory area/auditory association area (Brodmann's area 22)

Secondary auditory area is situated on the lateral surface of the superior temporal gyrus, slightly posterior to the primary auditory area which it surrounds (Fig. 27.1 ).

The primary and secondary auditory areas receive fibres from the medial geniculate body via the auditory radiation. The cochleae are bilaterally

represented. Therefore, a lesion in one cortex does not cause unilateral deafness.

## Functional areas in occipital lobe

### Primary visual area/striate area (area 17)

Primary visual area is situated mainly on the medial surface of the occipital lobe in the walls and floor of the posterior part of the calcarine sulcus (**postcalcarine sulcus**) and extends around the occipital pole onto the lateral surface of the occipital lobe as far as the **lunate sulcus** (Figs 27.1 and 27.2).

The most marked structural feature of the visual cortex is the presence of **white line/visual stria (of Gennari)**, hence the name – striate area.

### Secondary visual area (areas 18 and 19)

The cortex adjacent to the primary visual area on the medial and lateral surfaces of the occipital lobe is occupied by secondary visual area (visual association area).

The visual cortex receives afferent fibres from lateral geniculate body via optic radiations. The visual cortex receives fibres from temporal half of the ipsilateral retina and the nasal half of the contralateral retina, i.e., it registers impulses from opposite field of vision. Thus, right half of the field of vision is represented in the visual cortex of the left cerebral hemisphere and vice versa. It is also important to note that impulses from the superior retinal quadrants (inferior field of vision) pass to the superior wall of the calcarine sulcus, whereas the inferior retinal quadrants (superior field of vision) pass to the inferior wall of the calcarine sulcus.

The **macular area** which is the central area of retina and responsible for maximum visual acuity (*keenest vision*) has extensive cortical representation, occupying approximately posterior one-third of the visual cortex.

## White matter of cerebrum AN 62.3

The white matter of the cerebrum is a compact mass of a vast number of myelinated nerve fibres.

### Types of fibres in white matter

They are classified into the following three types, on the basis of the types of

connections they provide:

1. Association fibres
2. Commissural fibres
3. Projection fibres.

### **Association fibres**

The association fibres interconnect the different regions of the cerebral cortex in the same hemisphere (*intrahemispheric fibres*). These are of the following two types:

1. **Short association fibres**, which interconnect the adjacent gyri by hooking around the sulcus; hence, they are also called *arcuate fibres*.
2. **Long association fibres**, which travel for long distances and interconnect the widely separated gyri, namely, gyri of different lobes.

### **Commissural fibres**

The commissural fibres interconnect the identical cortical areas of the two cerebral hemispheres (*interhemispheric fibres*). The bundles of such fibres are termed commissures.

The important commissures of the brain are as follows:

1. Corpus callosum
2. Anterior commissure
3. Posterior commissure
4. Hippocampal commissure
5. Habenular commissure.

### **Corpus callosum (Fig. 27.3 )**

The corpus callosum is the **largest commissure of the brain**. It consists of approximately 100 million fibres.

**FIG. 27.3 ■** Corpus callosum. (A) Parts of corpus callosum as seen in median sagittal section of the cerebrum; (B) fibres of corpus callosum as seen in

transverse section of cerebrum through corpus callosum.

**External features of corpus callosum:** Corpus callosum forms a massive arched interhemispheric bridge in the floor of the *median longitudinal cerebral fissure* connecting the medial surfaces of the two cerebral hemispheres.

In sagittal section of cerebrum, it is seen as C-shaped mass of white fibres on the medial surface of the hemisphere forming the roof of the lateral ventricle (Fig. 27.3 ).

The concave inferior aspect of corpus callosum is attached with the convex superior aspect of the fornix by *septum pellucidum*.

**Parts of the corpus callosum:** The corpus callosum is divided from before backwards into the following four parts (Fig. 27.3 A):

1. **Genu:** It is thick curved anterior extremity of corpus callosum which lies 4 cm behind the frontal pole. The fibres of genu sweep (curve) forwards on either side into the anterior parts of the frontal lobes, forming a fork-like structure, the **forceps minor** (Fig. 27.3 B).
2. **Rostrum:** The genu extends downwards and backwards as a thin prolongation to join the lamina terminalis forming, rostrum of corpus callosum.
3. **Trunk:** The trunk is the main (middle) part of the corpus callosum between its thick anterior (genu) and massive posterior (splenium) extremities.
4. **Splenium:** The splenium is the massive posterior extremity of the corpus callosum, lying 6 cm in front of the occipital pole. The fibres of the splenium connect the parietal (posterior parts), temporal, and occipital lobes of the two hemispheres. The fibres connecting the occipital lobes sweep backwards on either side above the calcarine sulcus forming a large fork-like structure, the **forceps major** (Fig. 27.3 B).

**Functions of the corpus callosum:** The corpus callosum is largely responsible for **interhemispheric transfer of information** which is essential for bilateral responses and learning processes.

### **Anterior commissure**

The anterior commissure is a small round bundle of white fibres which crosses the midline in the upper part of the lamina terminalis, immediately in

front of the anterior column of the fornix and interventricular foramen.

Anterior commissure consists of two components:

1. A large **posterior neocortical component** , which interconnects the lower and anterior parts of the temporal lobes.
2. A smaller **anterior paleocortical component** , which interconnects the olfactory regions of the two hemispheres.

### Posterior commissure

The posterior commissure is a slender bundle of white fibres which crosses the midline through the inferior lamina of the stalk of pineal gland.

### Hippocampal commissure (commissure of fornix)

Hippocampal commissure interconnects the crura of fornix of the two sides and thus forms the **hippocampal formation** .

### Habenular commissure

The habenular commissure is a slender bundle of white fibres which crosses the midline through the superior lamina of the stalk of pineal gland.

### Projection fibres

The projection fibres connect the cerebral cortex to the subcortical centres (e.g., the corpus striatum, thalamus, and brainstem) and spinal cord. These fibres are of the following two types:

1. **Corticofugal fibres** , which *go* away from the cortex (cortical efferents) to centres in the other parts of the CNS.
2. **Corticopetal fibres** , which *come* to the cerebral cortex from the other centres in the CNS.

The projection fibres of neocortex constitute the *corona radiata* and *internal capsule*, whereas those of allocortex (i.e., archicortex and paleocortex) constitute the *fimbria* and *fornix*.

The most important bundles of projection fibres are: (1) **internal capsule** and (2) **fornix** .

### Internal capsule (Fig. 27.4 )

The internal capsule is a compact bundle of projection fibres between thalamus and caudate nucleus medially and lentiform nucleus laterally. It

consists of ascending and descending nerve fibres which connect the cerebral cortex to the brainstem and spinal cord.

**FIG. 27.4 ■** Main components of internal capsule and their constituent fibres. *Yellow , thalamocortical; green , corticopontine fibres; red , corticonuclear and corticospinal fibres; violet , corticorubral fibres .*

The afferent (sensory) fibres pass up from thalamus to the cerebral cortex, and efferent (motor) fibres pass down from the cerebral cortex to the cerebral peduncle of the midbrain.

These sensory and motor fibres of internal capsule are mainly responsible

for the sensory and motor innervation of the opposite half of the body.

### N.B.

The sensory fibres radiate from thalamus in different directions to reach the widespread areas of the cerebral cortex and constitute the *thalamic radiation*.

### CLINICAL CORRELATION

**Widespread effects of internal capsule lesions:** Because of high concentration of motor and sensory nerve fibres within the internal capsule, even a small lesion in internal capsule may produce widespread paralytic effects and sensory loss in the opposite half of the body.

### Shape and parts of internal capsule

In a horizontal section of the cerebral hemisphere, the internal capsule appears as a V-shaped compact bundle of white fibres with its concavity directed laterally (Fig. 27.4 ).

The internal capsule is divided into the following five parts (Fig. 27.4 ):

1. **Anterior limb** – between the head of caudate nucleus and anterior part of the lentiform nucleus.
2. **Posterior limb** – between the thalamus and the posterior part of the lentiform nucleus.
3. **Genu** – the bend between anterior and posterior limbs with concavity of the bend facing laterally.
4. **Retrolentiform part** – behind the lentiform nucleus.
5. **Sublentiform part** – below the lentiform nucleus.

### Constituent fibres of internal capsule

The constituent motor and sensory fibres in different parts of the internal capsule are summarized in Table 27.1 and shown in Figure 27.4 .

TABLE 27.1

### Constituent motor and sensory fibres in different parts of internal capsule

Part	Motor fibres	Sensory fibres
------	--------------	----------------

Anterior limb	Corticopontine fibres	Anterior thalamic radiation
Genu	Corticopontine fibres Corticonuclear and corticospinal fibres for head and neck	Superior thalamic radiation (anterior part only)
Posterior limb	Corticopontine fibres Corticospinal (pyramidal) fibres for upper limb, trunk and lower limb Corticorubral (extrapyramidal) fibres	Superior thalamic radiation
Retrolentiform part	Corticopontine fibres	Posterior thalamic radiation (optic radiation)
Sublentiform part	Corticopontine fibres	Inferior thalamic radiation (auditory radiation)

### Arterial supply of internal capsule

Different parts of the internal capsule are supplied by the following arteries:

1. **Anterior limb:** by medial striate branches of the anterior cerebral artery and lateral striate branches of the middle cerebral artery.
2. **Genu:** by recurrent artery of the Heubner or direct branches from internal carotid artery.
3. **Posterior limb:** by lateral striate branches of the middle cerebral artery and branches of the anterior choroidal artery.

### CLINICAL CORRELATION

**Lesions of internal capsule:** The internal capsule is frequently involved in the cerebrovascular disorders.

The most common cause of arterial haemorrhage is atheromatous degeneration of an artery in individuals suffering from high blood pressure.

The haemorrhage commonly occurs because of rupture of the Charcot's artery, larger lateral striate branch of the middle cerebral artery (also called *Charcot's artery of cerebral haemorrhage*), which supplies posterior limb of the internal capsule.

Damage to the internal capsule caused by *haemorrhage or infarction* , leads to loss of sensations and spastic paralysis (UMN type of paralysis) of the opposite half of the body (**contralateral hemiplegia** —[Fig. 27.5](#) ).

**N.B.**

Rupture of Charcot's artery of cerebral haemorrhage is the most common cause of the hemiplegia.

**FIG. 27.5** ■ Right sided spastic hemiplegia.

**Fornix**

The fornix is a large curved fibre bundle which connects hippocampus with mammillary body. It is described in detail on page 392 in [Chapter 28](#) .

## **Lateral ventricles AN 63.1**

There are two lateral ventricles, one in each cerebral hemisphere. Each lateral ventricle is a C-shaped cavity lined with ependyma within each cerebral hemisphere.

Each lateral ventricle communicates with the 3rd ventricle through the interventricular foramen (of Monro).

### **Parts of lateral ventricle (Fig. 27.6 )**

For descriptive purposes, each lateral ventricle is divided into four parts, namely

1. Central part
2. Anterior horn
3. Posterior horn
4. Inferior horn.

**FIG. 27.6 ■** Ventricular system of the brain showing different parts of lateral ventricle: (A) lateral view; (B) superior view.

### Central part

The central part or body lies mostly within the parietal lobe and extends from interventricular foramen in front to the splenium of the corpus callosum behind. In coronal section, it is triangular and presents floor, roof, and medial

wall.

The floor from lateral to medial side is formed by body of caudate nucleus, stria terminalis, thalamostriate vein, and thalamus. The roof is formed by the body of the corpus callosum and the medial wall is formed by septum pellucidum.

### **Anterior horn**

It is the anterior extension of the central part into the frontal lobe and lies in front of interventricular foramen and behind the posterior surface of the genu of corpus callosum.

It is triangular in coronal section and presents roof, floor, and anterior, medial, and lateral walls.

The roof is formed by anterior part of the body of corpus callosum, the floor by rostrum of corpus callosum, anterior wall by genu of corpus callosum. The medial and lateral walls are formed by septum pellucidum and head of caudate nucleus, respectively.

### **Posterior horn**

It is the backward extension of the central part into the occipital pole.

In coronal section, the posterior horn presents: medial wall, lateral wall, roof, and floor.

The medial wall consists of two convexities, the upper one – the *bulb of posterior horn* is formed by the forceps major of corpus callosum, and the lower one – the *calcar avis* is formed by the calcarine sulcus. The roof, lateral wall, and floor are formed by the tapetum of the corpus callosum.

### **Inferior horn**

It is the largest horn and is considered as direct continuation of the main ventricular cavity into the temporal lobe.

In coronal section, it appears as a transverse slit and presents the roof and the floor. The floor is formed medially by the hippocampus and laterally by collateral eminence. The lateral part of the roof is formed by tapetum of the corpus callosum and medial part by the tail of caudate nucleus and stria terminalis.

### **N. B.**

The area where inferior and posterior horns diverge is called *collateral trigone*.

## Choroid plexus and choroid fissure

On the medial aspect of the cerebral hemisphere, along the C-shaped line between diencephalon and hemisphere, medial wall of the central part and inferior horn of the lateral ventricle is made up of only ependyma. The pia mater covering the ependyma along this C-shaped line is invaginated by the fringe-like tuft of capillaries of blood vessels into the central part and inferior horn to form the choroid plexus of the lateral ventricle. The line of invagination of the **choroid plexus into the lateral ventricle** is called **choroid fissure**.

### Golden Facts to Remember

• <b>Largest part of the brain</b>	Cerebrum
• <b>Most conspicuous cerebral sulcus</b>	Lateral sulcus (of Sylvius)
• <b>Dominant cerebral hemisphere (in right-handed people)</b>	Left cerebral hemisphere
• <b>Largest bundle of commissural fibres of the brain</b>	Corpus callosum
• <b>Most important and largest bundle of projection fibres of the brain</b>	Internal capsule
• <b>Most common cause of hemiplegia</b>	Infarction of the posterior limb of the internal capsule
• <b>Largest part of the lateral ventricle</b>	Central part or body
• <b>Largest horn of the lateral ventricle</b>	Inferior horn
• <b>Most variable horn of the lateral ventricle</b>	Posterior horn
• <b>Island of Reil</b>	Insula (also called central lobe)
• <b>Most marked structural feature of the visual cortex</b>	Visual stria (of Gennari)

### CLINICAL CASE STUDY

A 57-year-old executive officer with a history of hypertension developed paralysis in the left side of his body. He was taken to the nearby neurocentre, where on examination the neurosurgeon found increased muscle tone, increased tendon reflexes, and positive Babinski sign on the affected side. The sensory examination revealed altered sensations on the affected side.

The CT scan of his head revealed a small lesion in his left cerebral hemisphere in the region of the internal capsule. He was diagnosed as a case of **right-sided hemiplegia** (Fig 27.5 , page 385).

### Questions

1. Whether the executive officer suffered from? UMN or LMN type of paralysis? Substantiate your answer with reasons.
2. Name the parts of the internal capsule and mention the part in which the lesion was likely to be located.
3. Which is the most commonly ruptured artery of the cerebral hemisphere?

### Answers

1. The UMN type of paralysis, because the typical features of upper motor neuron (UMN) type of paralysis are increased muscle tone, increased tendon reflexes, and positive Babinski sign.
2. The internal capsule consists of the following five parts: anterior limb, genu, posterior limb, sublenticular part, and retrolenticular part. The lesion was likely to be located in the posterior limb because it contains corticospinal fibres and fibres of superior thalamic radiation providing motor and sensory innervation to the opposite half of the body, respectively.
3. *Charcot's artery of cerebral haemorrhage* . It is the larger lateral striate (lenticulostriate) branch of the middle cerebral artery.

---

# Chapter 28: Basal nuclei and limbic system

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Enumerate parts and major components of basal ganglia and limbic lobe. **AN 62.4**
- Enumerate the basal nuclei. Describe corpus striatum in detail.
- Write short notes on: (a) caudate nucleus, (b) amygdaloid body, (c) fornix, and (d) hippocampus.
- Define limbic system and enumerate its components.
- Give the anatomical basis of Parkinsonism.

## Basal nuclei AN 62.4

The basal nuclei (or ganglia) are large subcortical masses of grey matter located inside the white matter in the basal part of the cerebral hemisphere.

### Parts

Anatomically, the term *basal ganglia* include:

- (a) **Corpus striatum**
  - ⊖ Caudate nucleus
  - ⊖ Lentiform nucleus
- (b) **Clastrum**
- (c) **Amygdaloid body** .

Functionally, basal ganglia also include **substantia nigra, red nucleus** ,

and **subthalamus** .

The basal nuclei are important in organizing and coordinating motor movements. The major function of the basal nuclei is to decrease muscle tone and inhibit unwanted muscular activity.

### Corpus striatum

The corpus striatum is situated lateral to the thalamus. Topographically, it is almost completely divided into the **caudate nucleus** and the **lentiform nucleus** by a band of nerve fibres, the *internal capsule*. However, anteroinferior ends of these nuclei remain connected by a few bands of grey matter across the anterior limb of the internal capsule. These bands give it a striated appearance, hence the name corpus striatum (Figs 28.1 and 28.2 ).

**FIG. 28.1 ■** Corpus striatum. (A) As seen from lateral aspect; (B) relationship of the corpus striatum to the internal capsule.

**FIG. 28.2 ■** Corpus striatum, thalamus, claustrum, and internal capsule – as seen in horizontal section of the cerebral hemisphere.

The lentiform nucleus consists of two parts: a darker lateral part *putamen* and a medial paler part *globus pallidus*.

Phylogenetically, corpus striatum forms two distinct functional units, the **paleostriatum** and the **neostriatum**.

The globus pallidus is relatively ancient and termed *paleostriatum* /*pallidum*. The caudate nucleus and putamen being recent in development, together form the *neostriatum* /*striatum*.

These features of the corpus striatum are summarized in [Flowchart 28.1](#).

## FLOWCHART 28.1 ■ Features of the corpus striatum.

### Caudate nucleus

Caudate nucleus is a large comma-shaped mass of grey matter, which surrounds the thalamus and is itself surrounded by the lateral ventricle. The whole length of its convexity projects into the cavity of lateral ventricle.

Its rounded anterior part in front of interventricular foramen is called its **head**. The head gradually and imperceptibly tapers caudally into the **body** and then into a **tail**, which merges at its anterior extremity with an almond-shaped mass of grey matter called *amygdaloid body* (Fig. 28.3).

**FIG. 28.3** ■ Caudate nucleus, amygdaloid body, and stria terminalis.

### Lentiform nucleus

Lentiform nucleus is a large lens-shaped (biconvex) mass of grey matter beneath the insula forming the lateral boundary of the internal capsule. In horizontal section of cerebrum, it appears wedge shaped with broad convex base directed laterally.

It is divided into two parts by a vertical plate of white matter (*external medullary lamina*): an outer darker part, the *putamen* and an inner lighter

part the *globus pallidus*.

The larger lateral part, the **putamen** consists of densely packed small cells, and is structurally similar to the caudate nucleus.

The **globus pallidus** is smaller medial part and consists of large (motor) cells. It is also known as *pallidum* as it appears pale in section (pallid = pale). The globus pallidus is further subdivided by an *internal medullary lamina of white matter* into outer and inner segments.

### Connections of corpus striatum

The striatum (caudate nucleus and putamen) is the receptive part, whereas globus pallidus is the efferent part (outflow centre) of the corpus striatum.

The striatum receives fibres mainly from the cerebral cortex, thalamus, and substantia nigra. The globus pallidus sends fibres to the thalamus, subthalamus, substantia nigra, reticular formation, and red nucleus.

Different pathways involve different neurotransmitters, which include dopamine, acetylcholine, glutamate, and  $\gamma$ -aminobutyric acid (GABA).

### Clastrum

Clastrum is a thin saucer-shaped mass of grey matter situated between the putamen and insula.

Its significance is not known.

### Amygdaloid body (or amygdala)

Amygdaloid body is an almond-shaped mass of grey matter in the temporal lobe, lying anterosuperior to the tip of inferior horn of lateral ventricle. It is situated deep to uncus, which serves as a surface landmark for its location.

The fibres arising from amygdaloid body form stria terminalis, which follow the inner curve of the caudate nucleus and terminate into septal area, anterior perforated substance, and anterior hypothalamic nuclei ([Fig. 28.3](#)). The stria terminalis is the main efferent tract of the amygdaloid body.

Developmentally, it is related to the basal nuclei, but functionally, it is included in the limbic system, and therefore, shares its functions (for details, see [Limbic System](#) on page 390).

### Substantia nigra and red nucleus

Substantia nigra and red nucleus are described in detail in [Chapter 24](#), pages 361 and 362.

### Subthalamus (subthalamic nucleus)

This is a small nucleus in the ventral part of the diencephalon, which looks like a biconvex lens in coronal section. It is located caudal to the lateral half of the thalamus and inferomedial to globus pallidus. It is separated from thalamus by a smaller nucleus called **zona incerta**.

## Functions of basal nuclei

The functions of the basal nuclei are as follows:

1. Concerned with planning and programming of voluntary movements.
2. Determine how rapidly a movement is to be performed and how large the movement must be.
3. Decrease muscle tone and inhibit unwanted muscular activity.
4. Regulate the muscle tone and thus help in smoothening the voluntary motor activities of the body.
5. Control automatic associated movements, such as swinging of arms during walking.
6. Control group of movements responsible for emotional expression.
7. Control reflex muscular activity.

## CLINICAL CORRELATION

**Lesions of basal ganglia:** The lesions of basal ganglia result in various forms of unwanted involuntary movements and disturbance in the muscle tone. These disorders include Parkinsonism, chorea, athetosis, and ballismus. The Parkinsonism being the most common disorder is described in detail in the following text.

- **Parkinsonism** (also called *Parkinson disease/paralysis agitans* [Fig. 28.4](#)): This disease usually occurs after 50 years of age because of deficiency of the neurotransmitter dopamine in the corpus striatum following a lesion in substantia nigra and/or its nigrostriate fibres.

*Characteristic features of Parkinsonism:*

- ⊖ Resting tremors
- ⊖ Lead-pipe or cogwheel type of muscular rigidity
- ⊖ Pill-rolling movements of hands
- ⊖ Mask-like face or loss of facial expression
- ⊖ Stiff, shuffling gait
- ⊖ Stooped posture
- ⊖ General slowing-down of movements and absence of associated

movements, such as arm swinging during walking.

**FIG. 28.4** ■ Clinical features of Parkinsonism.

## Limbic system AN 62.4

The word *limbus* means ring, the term **limbic system** is applied to the parts of the cortical and subcortical structures that form a ring around the upper end of the brainstem.

The limbic region was formerly called **rhinencephalon** because of its association to olfaction, but only a small part of it is actually concerned with smell.

Phylogenetically, limbic cortex is the oldest part of the cerebral cortex and is made up of primitive type of cortical tissue called **allocortex**, which consists of only three layers and surrounds the hilum of the cerebral hemisphere.

The limbic system plays a vital role in **abstract functions**, such as emotions, behaviour, drive, and memory.

## Functions of limbic system

The limbic system is functionally associated with the following neural activities:

1. Emotional aspects of behaviour together with visceral responses accompanying these emotions, particularly the reactions of fear and anger, and emotions associated with sexual behaviour that are necessary for:
  - (a) Survival of an individual including procuring of food and eating behaviour
  - (b) Survival of the species, including the sexual behaviour
2. Brain mechanisms responsible for recent memory.
3. Integration of olfactory, visceral, and somatic impulses reaching the brain.

### N.B.

Because of visceral responses to activities in the limbic system, it is also known as *visceral brain*. The main object of limbic system is to meet the needs of primitive life, i.e., food and sex.

## Components of limbic system

A large number of structures of the brain are included in the limbic system. However, a fairly accepted list of these structures is described here.

### Regions of grey matter in limbic system

#### Cortical structures

1. **Limbic lobe**, consisting of cingulate gyrus, isthmus, parahippocampal gyrus, and uncus (anterior part of the parahippocampal gyrus).
2. **Hippocampal formation** ([Fig. 28.5](#)), which includes hippocampus (cornu ammonis), dentate gyrus, gyrus fasciolaris, and indusium griseum.

**FIG. 28.5 ■** Limbic lobe and hippocampal formation.  
AN, anterior nucleus of thalamus; MB, mammillary body;  
MT, mammillothalamic tract.

### Subcortical nuclei

1. Amygdaloid nuclear complex (also called *amygdaloid body* )
2. Septal region and nuclei
3. Olfactory areas
4. Hypothalamus especially the mammillary bodies
5. Anterior nucleus of thalamus.

### Fibre bundles of the limbic system

1. Fornix
2. Mammillothalamic tract
3. Stria terminalis
4. Anterior commissure.

### Amygdaloid nuclear complex

Amygdaloid nuclear complex consists of lateral, central, and basal nuclei. It is an almond-shaped mass of grey matter underlying the rostral part of the parahippocampal gyrus on the anterior most part of the roof of the inferior horn of lateral ventricle.

Posteriorly, amygdaloid body becomes continuous with the tail of the caudate nucleus and stria terminalis ([Fig. 28.3](#) ).

## Connections

### Afferents

Main afferents to amygdaloid body are from primary olfactory regions.

### Efferents

**Stria terminalis** forms the main efferent tract of the amygdaloid body. It takes a circuitous route along with (but not functionally related to) the tail of caudate nucleus in close relation to the lateral ventricle until the level of anterior commissure, where majority of its fibres terminate in the septal area and anterior portion of the hypothalamus ([Fig. 28.3](#) ). The others join the anterior commissure and are distributed to the contralateral amygdaloid body.

In general, amygdaloid body plays an important role in controlling the somatic responses to internal needs, drives, or instincts. As part of it receives olfactory input, it is believed that the amygdaloid body plays an important role in smell-mediated sexual behaviour.

Stimulation of amygdaloid body produces excitability, fear, and rage. Bilateral damage of amygdaloid body reduces fear and increases sexual activity.

### N.B.

People in late 60s become pervasive in their sexual behaviour, probably because of atrophy of amygdaloid bodies.

## Hippocampal formation

The hippocampal formation consists of: (a) hippocampus, (b) dentate gyrus, (c) indusium griseum, gyrus fasciolaris, and (d) medial and lateral longitudinal striae.

## Hippocampus

Hippocampus (also called **Ram's horn** or **Ammon's horn** ) is an area of cerebral cortex that has rolled into the floor of the inferior horn of the lateral ventricle during foetal life. In an adult brain, it forms a longitudinal elevation in the floor of inferior horn of the lateral ventricle and is continuous medially with the subiculum and parahippocampal gyrus.

The name 'hippocampus', meaning 'sea horse', is derived from its appearance.

In frontal section, the hippocampus is C-shaped and its outline bears a resemblance to a Ram's horn, hence the name **Ram's horn** . It is also called **Ammon's horn** after an Egyptian deity with Ram's head. Its anterior extremity is expanded and bears few grooves and intervening ridges. Because of its resemblance to an animal's paw, it is termed **pes hippocampi** (pes = foot). Traced posteriorly, the hippocampus gradually narrows and ultimately ends beneath the splenium of corpus callosum.

The ventricular surface of the hippocampus is covered by a thin layer of white fibres called **alveus** . The fibres of alveus originate in the hippocampal cortex, course towards the medial border of hippocampus where they converge to form a narrow strip of white matter, the **fimbria of hippocampus** .

Phylogenetically, hippocampus represents the archicortex and consists of the following three layers:

1. Superficial molecular layer
2. Middle pyramidal cell layer
3. Deep polymorphic cell layer.

### **N.B.**

The *parahippocampal cortex* (neocortex) is made up of six layers. In the region known as subiculum, there is gradual transition from six-layered neocortex to the three-layered archicortex.

## **Connections**

### **Afferents**

Hippocampus receives fibres mainly from entorhinal area (area 28).

### **Efferents**

The fornix is the main efferent tract of the hippocampus.

The fibres leaving the hippocampus pass to:

- (a) The opposite hippocampus through the commissure of fornix/hippocampal commissure
- (b) The septal and anterior hypothalamic regions
- (c) The mammillary body, which sends impulses to cingulate gyrus through anterior nucleus of thalamus.

## Functions of hippocampus

1. Formerly hippocampus was regarded as the part of olfactory system but it has no direct connections with the sense of smell in humans.
2. In humans, it is an integrative centre, which influences endocrine and visceral functions and emotional states through its connections with hypothalamus, septal nuclei, and the cingulate gyrus.

It plays an important role in *recent memory* .

## Dentate gyrus, indusium griseum, and medial and lateral longitudinal striae

In the foetal brain, the **dentate gyrus** develops as a further extension of the hippocampus and occupies the interval between hippocampus and parahippocampal gyri, lying deep to fimbria. Its surface is toothed, hence the name **dentate gyrus** . When traced anteriorly, dentate gyrus runs medially across the inferior surface of the uncus. This part is called **tail of dentate gyrus** . The posterior end of dentate gyrus is continuous with the **splenial gyrus or gyrus fasciolaris** , which continues as a thin layer of grey matter over the corpus callosum called **indusium griseum** .

The indusium griseum is the vestigial grey matter and contains two delicate longitudinal bands of fibres buried in it, the **medial and lateral longitudinal striae** .

## Fornix

The fornix is a large bundle of projection fibres, which connects hippocampus with the mammillary body. It constitutes the sole efferent system of the hippocampus ([Fig. 28.6](#) ).

**FIG. 28.6 ■** Main parts of the fornix.

On the medial surface of the cerebral hemisphere, it is seen as an arched prominent bundle of white fibres below the corpus callosum, along the lower border of septum pellucidum.

There is one fornix in each cerebral hemisphere but two are so closely related/fused beneath the middle of the body of corpus callosum that they are usually described as a single structure.

### **Origin, course, and distribution of the fibres**

The fibres of fornix arise mainly from the pyramidal cells of the hippocampus and form a thin layer of white fibres on its ventricular surface called **alveus**.

The fibres of *alveus* collect on the medial margin of hippocampus to form a narrow strip of white matter, the **fimbria**, lying flat over the dentate gyrus. The fimbria becomes a rounded band, the **crus of fornix** as it arches upwards, medially, and forwards underneath the splenium of corpus callosum. The two crura, one of each hemisphere, curving over the thalamus, converge and unite in the midline beneath the trunk of corpus callosum to form the **body of fornix**.

Anteriorly, the body of fornix divides into two columns, the **columns of fornix**. Each column of fornix arches downwards towards the anterior commissure and forms the anterior boundary of interventricular foramen. Then it curves posteriorly through the hypothalamus to end in the mammillary body. These fibres being located posterior to anterior commissure are referred to as **postcommissural fornix**. Some fibres of column pass in front of anterior commissure to end in the septal area and anterior hypothalamic region, and so on, to constitute the **precommissural**

**fornix .**

**To summarize, main parts of the fornix are fimbria, crura, body, and anterior columns (Fig. 28.6 ).**

### **N.B.**

Fornix is the only tract of the cerebrum, which contains all the three types of its fibres such as projection fibres, commissural fibres, and association fibres.

## **Mammillothalamic tract**

**Mammillothalamic tract** , also called tract of **Félix Vicq d’Azyr** , is a prominent bundle of fibres, which carry impulses from mammillary body to the anterior nucleus of the thalamus.

### **Golden Facts to Remember**

• <b>Most common disease of the basal nuclei</b>	Parkinsonism
• <b>Great efferent pathway of hippocampus</b>	Fornix
• <b>Ammon’s horn/Ram’s horn</b>	Hippocampus
• <b>Main efferent tract of amygdaloid body</b>	Stria terminalis
• <b>Two main needs of primitive life</b>	Food and sex
• <b>Fibre bundle/neural tract of brain containing all three types of white fibres of brain</b>	Fornix

### **CLINICAL CASE STUDY**

A 65-year-old patient presented with resting tremors of the hands, mask-like facies, and shuffling gait. A careful physical examination by a neurologist revealed increased muscle tone and cogwheel type of rigidity of the joints. The patient had a stooped posture and his speech was slurred. It was also observed that he lacked associated movements (i.e., no swinging of arms during walking). A clinical diagnosis of **Parkinsonism** was made.

### **Questions**

1. What is the anatomical basis of Parkinsonism?
2. Deficiency of which neurotransmitter is found in this condition?
3. Enumerate characteristic clinical features of Parkinsonism.

## Answers

1. Parkinsonism occurs because of degeneration of nerve cells in substantia nigra or nigrostriate fibres.
2. Dopamine.
3. The characteristic clinical features of Parkinsonism are mask-like facies, pill-rolling movements of hands with resting tremors (i.e., slight shaking of hands when person is not performing a task), stooped posture, and stiff shuffling gait.

---

# Chapter 29: Blood supply of the brain

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Enumerate the four main arteries supplying the brain. List the branches of cerebral part of internal carotid and cranial part of vertebral arteries.
- Describe the formation, branches, and major areas of distribution of circle of Willis. **AN 62.6**
- Write short notes on: (a) circle of Willis, (b) basilar artery, (c) arterial supply of the superolateral surface of cerebral hemisphere, (d) internal cerebral veins, (e) great cerebral vein of Galen, and (f) superficial middle cerebral vein.
- Give the anatomical basis of: (a) subdural haemorrhage and (b) subarachnoid haemorrhage.

The brain is one of the most metabolically active organs of the body as it depends on aerobic metabolism of glucose.

Although the brain constitutes only 2% (one-fiftieth) of the total body weight, it receives 20% (one-fifth) of the total cardiac output and consumes 20% of the total O<sub>2</sub> used by the body.

The **cerebrovascular diseases** (thrombosis, embolism, and haemorrhage) are the third most common cause of death, and the neurological signs depend on the site of lesion. Therefore, an adequate knowledge of the blood supply of the brain is essential for proper diagnosis and treatment of these diseases.

## Arteries of the brain

The blood supply to the brain is provided by four arteries: two vertebral arteries and two internal carotid arteries (Fig. 29.1 ).

**FIG. 29.1** ■ Four arteries supplying the brain.

The **two vertebral arteries** enter the skull through the foramen magnum and unite at the lower border of the pons to form the *basilar artery*, which ascends in the midline on the ventral surface of the pons, and at its upper border terminates by dividing into right and left posterior cerebral arteries.

Each **internal carotid artery** enters the cranial cavity through carotid

canal and the superior part of the foramen lacerum. It then takes a sinuous course through the cavernous sinus, pierces the dural roof of the sinus, and ends immediately lateral to the optic chiasma in the region of anterior perforated substance by dividing into a larger middle cerebral artery and a smaller anterior cerebral artery.

### Circle of Willis (*circulus arteriosus*) AN 62.6

It is an anastomotic ring of arteries located at the base of the brain.

The branches of basilar and internal carotid arteries anastomose at the base of brain around the interpeduncular fossa forming a six-sided polygon of arteries called **circulus arteriosus or circle of Willis** (Fig. 29.2 ). The circle of Willis lies in the *interpeduncular subarachnoid cistern* and contributes to most of the arterial blood supply to the cerebrum.

**FIG. 29.2 ■** Circle of Willis. AM, anteromedial group; AL, anterolateral group; PM, posteromedial group; PL, posterolateral group of central branches of circle of Willis.

### Formation

The circle of Willis is formed:

*Anteriorly*, by the anterior communicating and the anterior cerebral arteries.

*Posteriorly*, by the basilar artery dividing into two posterior cerebral arteries.

*Laterally on each side*, by the posterior communicating artery connecting the internal carotid artery with the posterior cerebral artery.

### Functional significance

Normally, there is little or no mixing of bloodstreams of: (a) two vertebral arteries in the basilar artery, (b) two anterior cerebral arteries in the anterior communicating artery, and (c) internal carotid and posterior cerebral arteries in the posterior communicating artery. Therefore, right half of the brain is supplied by right vertebral and right internal carotid arteries, and left half of the brain is supplied by left vertebral and left internal carotid arteries.

However, if one of the major arteries forming the circle of Willis is blocked, the circle of Willis provides various alternative routes for **collateral circulation** like an **arterial traffic circle**.

### Branches of circle of Willis and their distribution

It gives rise to three types of branches:

- **Cortical**, which arise from anterior cerebral, middle cerebral, and posterior cerebral arteries (Fig. 29.3).
  - ◊ *Anterior cerebral artery* supplies most of the medial surface of cerebral hemisphere.
  - ◊ *Middle cerebral artery* supplies most of the superolateral surface of cerebral hemisphere.
  - ◊ *Posterior cerebral artery* supplies most of inferior surface and occipital lobe of cerebral hemisphere.

- **Central branches (Choroidal Branches)**

- *Central branches of anterior cerebral artery* supply preoptic and supraoptic regions of hypothalamus.
- *Central branches of middle cerebral artery* supply deep structures of cerebral hemisphere, i.e., basal ganglia.
- *Central branches of posterior cerebral artery* supply thalamus, hypothalamus, subthalamus, and so on.

**FIG. 29.3** ■ Arterial supply of the different surfaces of the cerebral hemisphere. (A) Superolateral surface; (B) medial surface; and (C) inferior surface.

## CLINICAL CORRELATION

- **Congenital cerebral aneurysms:** These occur mostly at the sites where two arteries join in the formation of the circle of Willis. The basic abnormality at these points is the congenital deficiency of the tunica media (elastic tissue) in the arterial wall. The aneurysms are berry

shaped; hence, they are generally termed as *berry aneurysms*.

- **Subarachnoid haemorrhage:** The subarachnoid haemorrhage commonly, but not exclusively, results from rupture of congenital berry aneurysms in the interpeduncular cistern.

The subarachnoid haemorrhage produces a sudden severe pain in head followed by mental confusion. The death may quickly occur, or the patient may survive the first bleeding only to die a few days or weeks later.

### **Branches of the cranial part of vertebral artery**

These are as follows:

1. **Posterior spinal artery** usually arises from *posterior inferior cerebellar artery*, but may arise directly from vertebral artery near medulla oblongata. It passes downwards on the posterior surface of the spinal cord after dividing into two branches; one along the medial side and the other along the lateral side of the dorsal roots of the spinal nerves.
2. **Posterior-inferior cerebellar artery** is the largest branch of the cranial (4th) part of the vertebral artery. It arises near the lower end of the olive, winds backwards around the medulla oblongata, and then ascends to the pontomedullary junction.
3. **Anterior spinal artery** is a small branch. It arises near the termination of the vertebral artery. It descends in front of the medulla and unites with its fellow of the opposite side – the lower end of the olive to form a single median trunk that descends along anterior longitudinal fissure of the spinal cord.
4. **Meningeal branches** are small and supply the dura mater of the posterior cranial fossa.
5. **Medullary arteries** are several minute vessels that supply the medulla oblongata.

### **Branches of the basilar artery**

These are as follows:

1. **Pontine branches** are numerous short, slender paramedian vessels, which pierce the pons to supply it.
2. **Anterior-inferior cerebellar artery** arises close to lower border of the pons and runs backwards, and laterally usually ventral to the 7th

and 8th cranial nerves. Then it forms a loop over the flocculus of the cerebellum and peeps into the internal acoustic meatus for a variable distance lying below the 7th and 8th cranial nerves. After exit from the meatus, it supplies the anterolateral portion of the inferior surface of the cerebellum.

3. **Labyrinthine artery** is a long slender branch which arises either from basilar artery but may also arise from anterior-inferior cerebellar artery. It accompanies the vestibulocochlear nerve and enters the internal auditory meatus to supply the internal ear. It is an end artery.
4. **Superior cerebellar artery** arises close to the superior border of the pons, runs laterally below the oculomotor nerve (which is interposed between this artery and the posterior cerebral artery) and winds round the cerebral peduncle below the trochlear nerve to reach the superior surface of the cerebellum, which it supplies.
5. **Posterior cerebral artery** passes laterally along superior border of the pons parallel to the superior cerebellar artery, curves around the midbrain to reach the medial surface of the cerebral hemisphere beneath the splenium of corpus callosum. The artery gives off central branches into the ventral surface of the midbrain and temporal lobe of the corresponding cerebral hemisphere. Then it passes towards the occipital pole giving cortical branches.

### **Branches of the cerebral part of internal carotid artery**

These are as follows:

1. **Ophthalmic artery** arises from internal carotid artery immediately after it comes out of cavernous sinus and makes a U-shaped bend. The ophthalmic artery enters the orbit through optic canal to supply structures of the orbit including eyeball.
2. **Posterior communicating artery** arises close to the termination of the internal carotid artery. It runs backwards and anastomoses with proximal part of the posterior cerebral artery.
3. **Anterior choroidal artery** is a long slender branch, which arises just distal to the origin of the posterior communicating artery. It courses backwards above and along the optic tract to enter the inferior horn of the lateral ventricle through the choroid fissure to end in the choroid plexus.
  - *Because of its long subarachnoid course and a relatively small*

*lumen, anterior choroidal artery is most susceptible to thrombosis and is often referred to as artery of cerebral thrombosis.*

4. **Anterior cerebral artery** is a smaller terminal branch of the internal carotid artery. It runs forwards and medially above the optic nerve to the commencement of the median longitudinal cerebral fissure, where it comes very close to its fellow of the opposite side and gets joined with it by a short transverse *anterior communicating artery*. The anterior cerebral artery then curves around the genu of corpus callosum.
  - The branches given off just distal to the anterior communicating artery supply medial part of the orbital surface of the frontal lobe.
  - The artery continues along the upper surface of the corpus callosum and gives branches, which supply whole of the medial surfaces of the hemisphere above the corpus callosum as far back as the parieto-occipital sulcus.
5. **Middle cerebral artery** is the larger terminal branch of the internal carotid artery. It appears to be the direct continuation of the internal carotid artery and carries approximately 30% of the carotid blood flow.

The middle cerebral artery first runs laterally in the stem of the lateral sulcus and then turns backwards and upwards in the posterior ramus of the lateral sulcus, where it breaks up into frontal, parietal, and temporal branches, which emerge from lateral sulcus and run towards the areas of their supply.

The branches of main arteries supplying the brain are summarized in [Table 29.1](#).

 **TABLE 29.1**

### Branches of main arteries of brain

Cerebral part of internal carotid artery	Cranial (4th) part of vertebral artery	Basilar artery
1. Ophthalmic artery	1. Meningeal arteries	1. Anterior-inferior cerebellar artery
2. Anterior cerebral artery	2. Anterior spinal artery	2. Labyrinthine artery
3. Middle cerebral artery	3. Posterior spinal artery	3. Pontine arteries

4. Posterior communicating artery	4. Posterior-inferior cerebellar artery	4. Superior cerebellar artery
5. Anterior choroidal artery	5. Medullary arteries	5. Posterior cerebral artery

It is interesting to note from [Table 29.1](#) that each main artery supplying the brain gives off **five sets of branches**, thus making a total of **15 sets**; of which, there are **three pairs of cerebral arteries (anterior, middle, and posterior)** and **three pairs of cerebellar arteries** (posteriorinferior, anteriorinferior, and superior).

### CLINICAL CORRELATION

**Cerebral thrombosis** most commonly affects the middle cerebral artery or its main branches because it is a direct continuation of the internal carotid artery.

## Arterial supply of cerebrum

The cerebrum is supplied by three pairs of cerebral arteries, i.e., anterior, middle, and posterior.

### Branching pattern of cerebral arteries

The cerebral arteries give three types of branches, i.e.:

1. Cortical branches
2. Central branches
3. Choroidal branches.

### Cortical branches

The cortical branches supply the outer portion of the cerebrum. The cortical vessels freely anastomose and form a network in the pia mater on the surface of the cerebral cortex. From this network branches arise and pierce the cortex at right angle. Once they enter the cortex, they become the *end arteries*. There are two types of these end arteries: (a) short, which confine themselves only to the cortex and (b) long, which pass through the cortex and reach outer portion of the white matter.

### Central branches

They are numerous slender thin-walled perforating branches, which supply centrally located parts of the cerebrum, i.e., corpus striatum and internal

capsule. They are *end arteries*. The central arteries arise in the region of arterial circle of Willis, and are arranged into the following four groups:

1. Anteromedial group
2. Anterolateral group (lateral striate arteries)
3. Posteromedial group
4. Posterolateral group.

### Choroidal arteries

The choroidal arteries form a network of capillaries which project into the ventricles after invaginating the layers of pia mater and ependyma forming **choroid plexuses** . They are as follows:

1. Anterior choroidal artery, a branch of internal carotid artery
2. Posterior choroidal artery, a branch of posterior cerebral artery.

### Arterial supply to different surfaces of cerebral hemisphere (Fig. 29.3 )

#### Arterial supply to superolateral surface (Fig. 29.3 A)

The superolateral surface of the cerebral hemisphere is supplied by the following arteries:

1. **Middle cerebral artery:** Most of the superolateral surface (approximately two-third) is supplied by the middle cerebral artery. The region of cerebral cortex supplied by it includes the greater parts of primary motor and sensory areas, and frontal eye field. In the left (dominant) hemisphere, it includes the Broca and Wernicke's speech areas.
2. **Anterior cerebral artery:** A narrow strip of the cerebral cortex (approximately 2.5 cm in width) adjoining superomedial border up to the parieto-occipital sulcus is supplied by anterior cerebral artery. The upper parts of primary motor and sensory areas lie in this region.
3. **Posterior cerebral artery:** A narrow strip along the lower border of temporal lobe (excluding temporal pole) and occipital lobe are supplied by **posterior cerebral artery** . The posterior parts of visual area fall in this area.

#### Arterial supply to medial surface (Fig. 29.3 B)

The medial surface of the cerebral hemisphere is supplied by the following arteries:

1. **Anterior cerebral artery:** Most of the medial surface (anterior two-third) is supplied by the anterior cerebral artery. The region of cerebral cortex supplied includes the parts of motor and sensory areas (paracentral lobule) concerned with perineum, leg, and foot.
2. **Middle cerebral artery:** Temporal pole of the temporal lobe is supplied by the middle cerebral artery.
3. **Posterior cerebral artery:** Occipital lobe is supplied by the posterior cerebral artery. The area supplied includes the visual cortex.

### Arterial supply to inferior surface (Fig. 29.3 C)

The inner surface of the cerebral hemisphere is supplied by the following arteries:

1. **Posterior cerebral artery:** Most of the inferior surface except the temporal pole is supplied by the posterior cerebral artery.
2. **Middle cerebral artery:** Lateral part of the orbital surface of the frontal lobe and temporal pole of the temporal lobe are supplied by the middle cerebral artery.
3. **Anterior cerebral artery:** Medial part of the orbital surface of the frontal lobe is supplied by the anterior cerebral artery.

### N.B.

Each surface of the cerebral hemisphere is supplied by three cerebral arteries, i.e., anterior, middle, and posterior.

Most of the superolateral surface is supplied by middle cerebral artery, most of the medial surface by the anterior cerebral artery, and most of the inferior surface by the posterior cerebral artery.

### CLINICAL CORRELATION

**Occlusion of middle cerebral artery:** The occlusion of middle cerebral artery occurs commonly. It produces following signs and symptoms:

- *Contralateral hemiplegia and hemianaesthesia* involving mainly the face and arm, due to involvement of most of the primary motor and sensory areas.

- *Aphasia*, if left dominant hemisphere is involved, due to involvement of motor and sensory speech areas.
- *Contralateral homonymous hemianopia*, due to involvement of optic radiation.

## Arterial supply to other parts of the brain

The arterial supply to other parts of the brain are as follows:

1. The **corpus striatum** and **internal capsule** are supplied mainly by central branches of middle cerebral artery and to some extent by the central branches of anterior cerebral artery.
2. The **thalamus** is supplied mainly by the central branches of posterior communicating, posterior cerebral, and basilar arteries.
3. The **midbrain** is supplied by the posterior cerebral, superior cerebellar, and basilar arteries.
4. The **pons** is supplied by the basilar, superior cerebellar, and anterior-inferior cerebellar arteries.
5. The **medulla oblongata** is supplied by the vertebral, anterior spinal, posterior spinal, posterior inferior cerebellar, arteries.
6. The **cerebellum** is supplied by the superior, anterior inferior, and posterior-inferior cerebellar arteries.

## Venous drainage of the brain

The veins of the brain drain into the intracranial dural venous sinuses, which eventually drains into the internal jugular veins of the neck.

The characteristic features of the venous drainage of the brain are as follows:

1. The venous return in the brain does not follow the arterial pattern.
2. The veins of the brain are extremely thin walled because of absence of muscular tissue in their walls.
3. The veins of the brain possess no valves.
4. The veins of the brain run mainly in the subarachnoid space.

The veins of the brain comprise cerebral veins, cerebellar veins, and veins of the brainstem.

## Cerebral veins

The cerebral veins are divided into external (superficial) and internal cerebral veins, which drain the external surfaces and the internal regions of the cerebral hemisphere, respectively.

### External cerebral veins

The external cerebral veins drain the surface (cortex) of the hemisphere and are divided into three groups, i.e.:

1. Superior
2. Middle
3. Inferior

### Superior cerebral veins (Fig. 29.4 )

The superior cerebral veins are approximately 8–12 and drain upper parts of superolateral and medial surfaces of the cerebral hemisphere. They ascend upwards, pierce the arachnoid mater, and traverse the subdural space to enter the superior sagittal sinus.

**FIG. 29.4** ■ Veins on the superolateral surface of the cerebral hemisphere.

The anterior veins open at right angle, whereas the posterior open obliquely against the flow of bloodstream in the superior sagittal sinus, thereby preventing their collapse by increased CSF pressure.

### **Middle cerebral veins**

The middle cerebral veins are four, two on each side: superficial middle cerebral vein and deep middle cerebral vein.

The **superficial middle cerebral vein** (Fig. 29.4 ) lies superficially in the lateral sulcus. Anteriorly, it runs forwards to drain into the cavernous sinus, whereas posteriorly, it communicates with the superior sagittal sinus via **superior anastomotic vein (of Trolard)** and with the transverse sinus via **inferior anastomotic vein (of Labbe)** .

The **deep middle cerebral vein** lies deep in the lateral sulcus on the insula along with middle cerebral artery. It runs downwards and forwards and joins the *anterior cerebral vein* to form the **basal vein** .

### **Inferior cerebral veins**

The inferior cerebral veins are many in number but smaller in size. They drain the inferior surface and lower parts of medial and superolateral surfaces of the cerebral hemisphere into nearby intracranial dural venous sinuses, for example, transverse sinus.

### **Other veins**

#### **Anterior cerebral vein**

It accompanies the anterior cerebral artery around the corpus callosum and drains the parts of medial surface, which cannot be drained into the superior and inferior sagittal sinuses.

#### **Basal vein (of rosenthal)**

It is formed at the base of the brain in the region of anterior perforated substance by union of three veins: *anterior cerebral*, *deep middle cerebral*, and *striate veins* . The striate veins emerge from the anterior perforated substance.

The basal vein runs posteriorly around the midbrain, medial to the uncus and parahippocampus, and terminates into the **great cerebral vein (of Galen)** below the splenium of corpus callosum.

Besides the formative three veins, the basal vein receives the tributaries from:

1. Cerebral peduncle
2. Uncus and parahippocampus
3. Structures of interpeduncular fossa
4. Optic tract and olfactory trigone
5. Inferior horn of the lateral ventricle.

### Internal cerebral veins

There are two **internal cerebral veins** located one on either side of midline in the tela choroidea of the 3rd ventricle (Fig. 29.5 ).

**FIG. 29.5** ■ Formation, course, and tributaries of the

internal cerebral veins.

Each internal cerebral vein is formed at the **interventricular foramen (of Monro)** by the union of three veins: thalamostriate, septal, and choroidal. The two internal cerebral veins run posteriorly, one on either side of midline, between the two layers of tela choroidea of 3rd ventricle and unite together beneath the splenium of corpus callosum to form the **great cerebral vein (of Galen)**, which empties into the straight sinus.

The **thalamostriate, septal, and choroidal veins** are the most important deep veins of the cerebrum. As their names imply, the thalamostriate (striothalamic) vein drains the thalamus and basal ganglia; the septal vein drains the septum pellucidum, and the choroidal vein drains the choroids plexus.

### **Great cerebral vein (of Galen)**

Great cerebral vein is a single vein (approximately 2 cm in length). It is formed by the union of two internal cerebral veins below and behind the splenium of corpus callosum. It immediately receives the two basal veins, and after a short backward course, it joins inferior sagittal sinus to form the **straight sinus**.

The tributaries of the great cerebral vein are as follows:

1. Internal cerebral veins
2. Basal veins
3. Veins from colliculi (tectum of midbrain)
4. Veins from cerebellum and adjoining parts of the occipital lobes of the cerebrum.

## **Venous drainage of different surfaces of cerebral hemisphere**

### **Venous drainage of superolateral surface (Fig. 29.4 )**

Superolateral surface of the cerebral hemisphere is drained by the following veins:

1. **Superior cerebral veins:** They drain the upper part into the *superior sagittal sinus*.
2. **Inferior cerebral veins:** They drain the lower part into the *superficial middle cerebral vein*; however, some from the posteroinferior part drain into the *transverse sinus*.

## Venous drainage of inferior surface

Inferior surface of the cerebral hemisphere is drained by the inferior cerebral veins:

1. **Inferior cerebral veins from the orbital part:** They drain into the superficial middle cerebral, and anterior cerebral veins.
2. Inferior cerebral veins from the tentorial part: They drain into:
  - (a) Venous sinuses at the base of skull, i.e., cavernous, superior petrosal, straight, and transverse sinuses
  - (b) Superficial middle cerebral vein, which drains into cavernous sinus and basal vein that drains into the straight sinus

## Venous drainage of medial surface

Medial surface of the cerebral hemisphere is drained by the following veins:

1. **Superior cerebral veins:** They drain the upper part into superior sagittal sinus.
2. **Inferior cerebral veins:** They drain the lower part into the inferior sagittal sinus.
3. **Some of the veins from the posterior part:** These veins drain into the great cerebral vein.
4. **Anterior cerebral vein:** It drains the anterior part.

### N. B.

In conclusion, superficial veins drain mainly into the superior sagittal sinus, which ultimately drains into the right internal jugular vein. On the contrary, deep veins drain mainly into the great cerebral vein, which ultimately drains into the left internal jugular vein.

## CLINICAL CORRELATION

**Subdural haemorrhage:** It occurs because of rupture of cerebral veins in the subdural space. The cerebral veins while traversing the subdural space en route to drain into the dural venous sinuses have little support and are torn following moderate trauma on head. The superior cerebral veins are most commonly torn, where they enter the superior sagittal sinus. The cause is usually a blow on the front or back of the head, resulting in excessive anteroposterior displacement of the brain within the skull. Consequently, cerebral veins in the subdural space (called *bridging veins*) are unduly

stretched and torn. The subdural haemorrhage is generally extensive because of the loose attachment between the dura and arachnoid.

### Golden Facts to Remember

• <b>Most metabolically active organ in the body</b>	Brain
• <b>Circle of Willis</b>	Polygonal arterial anastomosis at the base of the brain
• <b>Most common congenital anomaly of circle of Willis</b>	Hypoplasia
• <b>Commonest cause of subarachnoid haemorrhage</b>	Rupture of berry aneurysms in the circle of Willis
• <b>Largest branch of cranial part of the vertebral artery</b>	Posterior inferior cerebellar artery
• <b>Artery of cerebral thrombosis</b>	Anterior choroidal artery
• <b>Artery of cerebral haemorrhage</b>	Charcot's artery (larger lateral striate branch of middle cerebral artery)
• <b>Most of the superolateral surface of the cerebral hemisphere is supplied by</b>	Middle cerebral artery
• <b>Most of the medial surface of the cerebral hemisphere is supplied by</b>	Anterior cerebral artery
• <b>Most of the inferior surface of the cerebral hemisphere is supplied by</b>	Posterior cerebral artery
• <b>Commonest cause of subdural haemorrhage</b>	Rupture of superior cerebral veins ( <i>bridging veins</i> )

### CLINICAL CASE STUDY

A 65-year-old individual who was suffering from chronic high blood pressure suddenly suffered from contralateral hemiplegia and hemianaesthesia with loss of speech. He was taken to the hospital, where he was diagnosed as a case of **cerebral stroke** .

### Questions

1. What is cerebral stroke?
2. Name the arteries which supply the cerebral hemisphere.
3. Which cerebral artery is likely to be involved in the given case?
4. What are the types of cerebral stroke?
5. What are the types of cerebral stroke?
6. What are the types of ischaemic cerebral stroke?

## Answers

1. A neurological deficit that follows the deprivation of the cerebral blood flow.
2. Anterior, middle, and posterior cerebral arteries.
3. Left middle cerebral artery, because it supplies the motor speech area.
4. There are two main categories of cerebral stroke:
  - a) Those caused by bleeding into the brain – 20%
  - b) Those caused by blockage of blood vessel in brain or neck – 80%.
5. They are of two types:
  - a) Ischaemic stroke
  - b) Haemorrhagic stroke.
6. There are two types of ischaemic strokes:
  - a) Thrombotic stroke
  - b) Embolic stroke.

---

# Chapter 30: Surface anatomy of head, neck and brain

---

## Specific learning objectives

---

**After studying this chapter, the student should be able to:**

- Do the surface marking of parotid duct. **AN 43.6**
- Do the surface marking of thyroid gland. **AN 43.6**
- Do the surface marking of great vessels of neck. **AN 43.6**
- Do the surface marking of inferior alveolar and lingual, and accessory nerve. **AN 43.6**
- Do the surface marking of accessory nerve.
- Do the surface marking of pterion. **AN 43.6**

## Head and neck

Surface landmarks of different regions of head and neck are described in the respective chapters.

### Parotid gland **AN 43.6**

The parotid gland is marked on the surface by joining following four points (**Fig. 30.1**).

1. Put a point 'a' on the upper border of the head of mandible.
2. Put a point 'b' just above the centre of the masseter muscle.
3. Put a point 'c' 2 cm below and behind the angle of mandible.
4. Put a point 'd' on the mastoid process.
  - The upper border/superior border is marked by a line joining the point 'a' and 'b'. This line is concave and its concavity directed

upwards backwards across the lobule of the ear.

- The anterior border is marked by a line joining the points a, b, and c. These lines show slight convexity anteriorly.
- The posterior border is marked by a line joining the points d and c.

**FIG. 30.1** ■ Surface marking of parotid gland and parotid duct.

## Parotid duct

It is marked on the surface as follows (**Figs 30.1 , 30.3**):

First mark the following two points.

- Put a point '1' on the lower part of the tragus of ear.
- Put a point '2' midway between the ala of the nose and red margin of the upper lip.

Now draw the line joining points 1 and 2. The middle third of this line represents the parotid duct.

## Facial artery in the face AN 43.6

The facial artery is marked on the face as follows ([Fig 30.2](#)):

- Put a point 'a' on the base of mandible at the anterior border of masseter muscle.
- Put a point 'b' on face about 1.25 cm lateral to the angle of mouth.
- Put a point 'c' at the medial angle of eye.

**FIG. 30.2 ■** Surface marking of facial artery on face.

Join the above 3 points by a tortuous line to represent facial artery on face.

## Pterion AN 43.6

It has already been done in [chapter 2](#) on Osteology of Head and Neck.

## Facial nerve AN 43.6

The facial nerve is marked on the surface as follows ([Fig. 30.3](#)):

- Put a point 'a' at the middle of the anterior border of mastoid process.  
(Note stylomastoid foramen lies 2 cm deep to this point.)
- Put a point 'b' behind the neck of mandible.
- Now join the points 'a' and 'b' by a horizontal line passing across the ear lobule.

**FIG. 30.3** ■ Surface marking of facial nerve and submandibular salivary gland.

### N.B.

At point 'b', facial nerve divides into five branches.

In general, transparotid course of facial nerve and direction of its buccal

branch is indicated by a line drawn forward parallel and below the parotid duct.

### **Submandibular gland AN 43.6**

It is marked on the surface as an oval area over the posterior half of the base of mandible as follows ([Fig. 30.3](#)):

- Put a point 'A' on the angle of mandible.
- Put a point 'B' on the lower border of midway between its angle and symphysis menti.
- Put a point 'C' between points 'A' and 'B'.
- Put a point 'D' 1.5 cm above point 'C'.
- Draw a line 'E' to indicate greater cornu of hyoid bone.

Now draw an oval area by joining points A, D, B, and touching line E to show the surface projection of submandibular salivary gland.

### **Mandibular and inferior alveolar nerves**

These are marked on the surface as follows ([Fig. 30.4](#)):

- Put a point 'a' on the centre of zygomatic arch.
- Put a point 'b' on the centre of the masseter muscle. (Note this point represents the mandibular foramen.)
- Place a point 'c' midway between upper and lower borders of the mandible below the interval between the premolar teeth. (Note this point represents the mental foramen.)

**FIG. 30.4** ■ Surface marking of mandibular, inferior alveolar, and lingual nerves.

Now draw a line joining these points with concavity directed upwards and forwards. The upper vertical part of the line represents the mandibular nerve, whereas remaining distal part of this line represents the inferior alveolar nerve.

## Lingual nerve

It is marked on the surface as follows:

- Put a point 'A' on lower border of zygomatic arch opposite the posterior part of mandibular notch.
- Put a point 'B' a little below and behind the 3rd molar tooth/last molar tooth.

Join these points by line directed forwards with an upward concavity and continue it along the body of mandible. This line represents lingual nerve.

## Thyroid gland AN 43.6

The isthmus and lobes of thyroid gland are marked on anterior aspect of the neck as follows (Fig. 30.5 ).

**FIG. 30.5** ■ Surface marking of the thyroid gland.

### Isthmus

It is marked on the surface as follows:

- Draw 1.5 cm long horizontal line across the trachea, 1 cm below the arch of the cricoid cartilage to represent the upper border of isthmus.
- Draw another transverse line 2.5 cm below the arch of thyroid cartilage to represent the lower border of isthmus.

### Lateral lobes

- Put a point 'A' 1 cm below the lateral end of the lower border of isthmus.
- Put another point 'B' 2.5 cm below and lateral to the outer end of the lower border of isthmus.
- Put a point 'C' a little in front of the anterior border of sternocleidomastoid at the level of laryngeal prominence to represent the extent of upper pole.

## Brachial plexus

The location of supraclavicular part of brachial plexus is located at the root of neck as follows (Fig. 30.6 ):

- Put a point 'a' on the anterior border sternocleidomastoid (sternal head) at the level of cricoid cartilage.
- Put a point 'b' on the midpoint of upper border of clavicle.

**FIG. 30.6 ■** Surface marking of brachial plexus and spinal accessory nerve. CC, Cricoid cartilage.

The line joining these points represents the upper limit of the brachial plexus.

## Spinal accessory nerve

It is marked on the surface as follows (Fig. 30.6 ):

- Put a point 'c' at the anteroinferior part of the tragus.
- Put a point 'd' at the tip of transverse process of atlas.
- Put a point 'e' on the posterior border of sternocleidomastoid at the junction of its upper one-third and lower two-third.

- Put a point 'f' on the anterior border of trapezius 6 cm above the clavicle.

The line joining these points represents the spinal accessory nerve.

## Subclavian artery

It is marked on the surface as follows (Fig. 30.7):

- Put a point 'a' on sternoclavicular joint.
- Put a point 'b' on the middle of the lower border of clavicle.
- Put a point 'c' 2 cm above the clavicle midway between the 1st and 2nd points.

**FIG. 30.7 ■** Surface marking of subclavian, common carotid, internal carotid, and external carotid arteries.

Join these points by broad curved line with its convexity facing upwards.

## **Common carotid artery AN 43.6**

It is marked on the surface as follows:

- Put a point 'a' on the sternoclavicular joint.
- Put a point 'd' on the anterior border of the sternocleidomastoid muscle at the level of upper border of thyroid cartilage.

Join these points by broad lines to represent the common carotid artery.

## **External carotid artery AN 43.6**

It is marked on the surface as follows ([Fig. 30.7](#)):

- Put a point 'd' on the anterior border of sternocleidomastoid at the level of the upper border of thyroid cartilage.
- Put a point 'e' midway between the tip of the mastoid process and angle of mandible.

Join these points by broad line slightly convex forwards in the lower half and slightly convex backwards in the upper half to represent the external carotid artery.

## **Internal carotid artery AN 43.6**

It is marked on the surface as follows ([Fig. 30.7](#)):

- Put a point 'd' on the anterior border of sternocleidomastoid at the level of upper border of thyroid cartilage.
- Put a point 'f' on the posterior border of the condyle of mandible.

Join these points by broad line to represent the internal carotid artery.

## **External jugular vein AN 43.6**

The surface markings of external jugular vein are done as follows ([Fig. 30.8](#)):

- Put a point 'a' below the angle of mandible.
- Put a point 'b' on the middle of the upper border of clavicle.

**FIG. 30.8 ■** Surface marking of external jugular, internal jugular, and subclavian veins.

A line extending downwards and backwards from point 'a' to 'b' represents the external jugular vein.

### Internal jugular vein AN 43.6

It is marked on the surface as follows:

- Put a point 'A' on ear lobule.
- Put a point 'B' on the medial end of clavicle.

Join these points by a broad line to represent the internal jugular vein.

### **N.B.**

Marking a dilatation at the lower end of this line between sternal and clavicular heads of sternocleidomastoid represents the inferior bulb of the

internal jugular vein.

## Subclavian vein AN 43.6

It is marked on the surface as follows (Fig. 30.8 ):

- Put a point 'd' a little medial to the midpoint of the lower border of the clavicle.
- Put a point 'c' on the medial edge of the clavicular head of sternocleidomastoid.

Join these points by a broad curved line with its convexity facing upwards.

## Brain

Surface landmarks of different regions are described in respective chapters.

### Superolateral surface of cerebrum

It is marked on the side of head by marking its superciliary, superomedial, temporal, and inferolateral borders (Fig. 30.9 ).

**FIG. 30.9 ■** Surface marking of superolateral surface of

cerebral hemisphere.

### **Superomedial border**

- Put a point 'a' just above and lateral to the nasion.
- Mark another point 'b' a little above and lateral to the inion.

Join these two points by a paramedian line to mark superomedial border.

### **Superciliary border**

- Put a point 'c' on the zygomatic process of frontal bone.
- Put a point 'd' at the pterion.

Draw a line from point 'c' to arch upwards to reach point 'a' and laterally a little above the eyebrow to reach the point 'd'.

### **Temporal pole**

- Put a point 'e' on the middle of the upper border of the zygomatic arch.

Draw a line to join points 'd' and 'e'.

### **Inferolateral border**

Draw a line backwards from the point 'e' to cross the auricle above the external auditory meatus and then to descend slightly to join the point 'b'.

## **Central and lateral cerebral sulci**

### **Central sulcus (Fig. 30.9 )**

- Put a point 'f' 1.2 cm (a finger's breadth) behind the mid-point of the paramedian line.
- Put a point above the point h.

Draw a line from the point 'f' running downwards and medially for approximately 9 cm with somewhat sinuous course and making an angle of 70° with the median plane as it joins the second point.

## Lateral sulcus (posterior ramus) (Fig. 30.9 )

- Put a point 'g' 4.5 cm above and lateral to point 'e'.
- Put a point 'h' a finger's breadth above the auricle.
- Put a point 'I' 1.2 cm below the parietal eminence.

Draw a line from point 'g' going backwards with an upward inclination to point 'h', then curve the line sharply upwards to end at the point 'I'.

## Functional areas of cerebral cortex

These are marked on the surface as given (Fig. 30.10 ).

**FIG. 30.10** ■ Surface marking of functional areas of cerebral cortex.

### **Motor speech area**

A finger tip placed just above the pterion on the left side represents the location of motor speech area (Broca's area).

### **Primary motor area**

A breadth of finger, placed in front of central sulcus represents the location of primary motor area.

### **Primary sensory area**

A breadth of finger, placed behind the central sulcus represents the primary sensory area.

### **Auditory area**

Two fingertips placed together side by side a little above and in front of the auricle represent auditory area.

### **Visual area**

A fingertip placed on the side of skull above external occipital protuberance represents visual area.

---

# Multiple choice questions

---

# Section I Head and neck

## Chapter 1

1. The smooth non-hairy area on forehead between the eyebrows is called:
  - Ⓐ Bregma
  - Ⓑ Glabella
  - Ⓒ Nasion
  - Ⓓ Medial canthus
2. The tragus of auricle is located in:
  - Ⓐ Frontal region of head
  - Ⓑ Nasal region of head
  - Ⓒ Temporal region of head
  - Ⓓ Zygomatic region of head
3. The most prominent part of occipital regions of the head is called:
  - Ⓐ Inion
  - Ⓑ Opisthocranium
  - Ⓒ Superior nuchal lines
  - Ⓓ Basion
4. Select **incorrect statement** regarding the auricle of the ear:
  - Ⓐ It helps to collect the sound waves
  - Ⓑ The upper end of helix lies at the level of lateral canthus of eye
  - Ⓒ The lobule is approximately at the level of the apex of the nose
  - Ⓓ The tragus is located anterior to the opening of external auditory meatus
5. Regarding lips, which of the following statement is **not correct**:
  - Ⓐ Each lip is demarcated from the surrounding skin by vermillion border
  - Ⓑ The philtrum is a triangular median depression in upper lip
  - Ⓒ The width of lips is approximately the same as that between the two irises
  - Ⓓ The lower lip is separated from the chin by labial commissure
6. All of the following structures can be palpated in anterior median region of the neck **except**:
  - Ⓐ Hyoid bone
  - Ⓑ Thyroid cartilage
  - Ⓒ Transverse process of atlas vertebra

- ⌘d) Cricoid cartilage
7. The junction between labial/buccal mucosa and alveolar mucosa is called:
- ⌘a) Mucogingival junction
  - ⌘b) Mucobuccal fold
  - ⌘c) Vermillion border
  - ⌘d) Labial frenulum
8. Floor of the mouth presents all of the following features **except**:
- ⌘a) Sublingual papillae
  - ⌘b) Sublingual folds
  - ⌘c) Parotid papillae
  - ⌘d) Frenulum linguae
9. A midline ridge of tissue on the oral aspect of the hard palate is called:
- ⌘a) Incisive papilla
  - ⌘b) Palatine rugae
  - ⌘c) Median palatine raphe
  - ⌘d) Sulcus terminalis
10. All of the following structures traverse through the anterior compartment of the neck **except**:
- ⌘a) Digestive tract
  - ⌘b) Respiratory tract
  - ⌘c) Internal jugular veins
  - ⌘d) Spinal cord
11. Into which cervical triangles does the sternocleidomastoid divide the neck:
- ⌘a) Medial and lateral
  - ⌘b) Superior and inferior
  - ⌘c) Anterior and posterior
  - ⌘d) Proximal and distal

## Answers

1. **b** , 2. **c** , 3. **b** , 4. **b** , 5. **d** , 6. **c** , 7. **b** , 8. **c** , 9. **c** , 10. **d** , 11. **c**

## Chapter 2

1. Bones of the skull which permit free movement are all **except**:
- ⌘a) Mandible
  - ⌘b) Malleus
  - ⌘c) Incus

- ❑(d) Vomer
2. The area of the lateral aspect of skull that overlies anterior division of middle meningeal artery is called:
- ❑(a) Bregma
  - ❑(b) Asterion
  - ❑(c) Pterion
  - ❑(d) Inion
3. Regarding pterion, all of the following statements are true **except**:
- ❑(a) It overlies the posterior division of middle meningeal artery
  - ❑(b) It is region where four bones meet
  - ❑(c) It is located 4 cm above the midpoint of zygomatic arch
  - ❑(d) Bones meeting at pterion form 'H-shaped suture'
4. Regarding spine of sphenoid, all of the following statements are true **except**:
- ❑(a) It is located on the base of skull posterolateral to the foramen spinosum
  - ❑(b) It is related to auriculotemporal and chorda tympani nerves
  - ❑(c) It provides attachment to levator palatini muscle
  - ❑(d) It provides attachment to sphenomandibular ligament
5. All of the following structures pass through foramen ovale **except**:
- ❑(a) Mandibular nerve
  - ❑(b) Anterior division of middle meningeal artery
  - ❑(c) Lesser superficial petrosal nerve
  - ❑(d) Emissary vein connecting pterygoid venous plexus to cavernous sinus
6. Regarding mastoid process, all of the following statements are correct **except**:
- ❑(a) It is absent at birth
  - ❑(b) It begins to develop at the end of the 2nd year after birth
  - ❑(c) It contains tympanic cavity
  - ❑(d) It provides attachment to posterior belly of digastric
7. All of the following are common sites of fracture of the mandible **except**:
- ❑(a) Neck of mandible
  - ❑(b) Angle of mandible
  - ❑(c) Canine region of the body
  - ❑(d) Symphysis menti
8. All of the following foramina are present in the greater wing of

sphenoid **except:**

- Ⓐ Foramen rotundum
- Ⓑ Foramen ovale
- Ⓒ Foramen lacerum
- Ⓓ Foramen spinosum

9. Which of the following bones is not a sutural bone?

- Ⓐ Epipteric bone
- Ⓑ Inca bone
- Ⓒ OS Kerckring
- Ⓓ Interparietal bone

10. In articulated skull, maxillary hiatus is reduced in size by all of the following bones **except:**

- Ⓐ Uncinate process of ethmoid
- Ⓑ Descending process of lacrimal
- Ⓒ Horizontal palate of palatine
- Ⓓ Maxillary process of inferior nasal concha

## Answers

1. **d** , 2. **c** , 3. **a** , 4. **c** , 5. **b** , 6. **c** , 7. **d** , 8. **c** , 9. **d** , 10. **c**

## Chapter 3

1. Which layer of scalp is regarded as the 'dangerous layer':

- Ⓐ Subcutaneous layer
- Ⓑ Aponeurotic layer
- Ⓒ Layer of loose areolar tissue
- Ⓓ Pericranium

2. Select the **incorrect statement** about the scalp:

- Ⓐ It extends posteriorly up to superior nuchal line
- Ⓑ Epicranial aponeurosis forms its second layer
- Ⓒ Its motor supply is derived from facial nerve
- Ⓓ Its vessels fail to retract if cut

3. All of the following nerves innervate the posterior quadrant of the scalp **except:**

- Ⓐ Auriculotemporal
- Ⓑ Great auricular
- Ⓒ Greater occipital
- Ⓓ Lesser occipital

4. All of the following arteries supply anterior quadrant of the scalp

**except:**

- Ⓐ Supratrochlear
- Ⓑ Supraorbital
- Ⓒ Posterior auricular
- Ⓓ Superficial temporal

5. Superficial surface of temporal fascia is related to all of the following structures **except:**

- Ⓐ Auriculotemporal nerve
- Ⓑ Great auricular nerve
- Ⓒ Superficial temporal vessels
- Ⓓ Temporal branches of facial nerve

6. Regarding muscles of facial expression, which of the following statements is **incorrect:**

- Ⓐ They are present in the superficial fascia
- Ⓑ They are developed from first pharyngeal arch
- Ⓒ Their motor supply is derived from facial nerve
- Ⓓ Morphologically they represent panniculus carnosus

7. Regarding Bell's palsy, which of the following statements is **not correct:**

- Ⓐ It is a lower motor neuron type of paralysis of facial muscles
- Ⓑ The upper facial muscles are not affected
- Ⓒ It occurs due to compression of facial nerve in the facial canal
- Ⓓ It leads to accumulation of food in the vestibule of mouth

8. Regarding lacrimal gland, which of the following statements is **not correct:**

- Ⓐ It consists of larger orbital and smaller palpebral part
- Ⓑ It is a mucous gland
- Ⓒ It receives its secretomotor supply through lacrimal nerve
- Ⓓ The two parts of lacrimal glands are separated from each other by levator palpebrae superioris

9. Regarding eyelids which of the following statements is **not correct:**

- Ⓐ Tarsi form the skeleton of the eyelids
- Ⓑ Free margin of eyelids carries eyelashes along its whole extent
- Ⓒ Openings of tarsal glands are present along the posterior edge of free margins of eyelids
- Ⓓ Openings of ciliary glands are located along anterior edge of the free margin of eyelids

## Answers

1. **c** , 2. **b** , 3. **a** , 4. **c** , 5. **b** , 6. **b** , 7. **b** , 8. **b** , 9. **b**

## Chapter 4

1. Regarding skin of neck, all of the following statements are correct

**except:**

- Ⓐ Cleavage lines of skin in the neck are disposed transversely
- Ⓑ It receives cutaneous innervation from C1 to C7 spinal nerves
- Ⓒ It receives cutaneous innervation from C2 to C4 spinal nerves
- Ⓓ It is thin and drains its lymph into superficial lymph nodes

2. Regarding platysma, all of the following statements are correct

**except:**

- Ⓐ It is present deep to investing layer of deep cervical fascia
- Ⓑ Morphologically it represents panniculus carnosus
- Ⓒ It is innervated by the facial nerve
- Ⓓ Its contraction relieves the pressure of skin on superficial veins of the neck

3. All of the following statements about external jugular vein are correct

**except:**

- Ⓐ It is formed by the union of posterior division of retromandibular vein and posterior auricular vein
- Ⓑ It crosses sternocleidomastoid on its superficial aspect
- Ⓒ It pierces the deep cervical fascia about 2.5 cm above the clavicle
- Ⓓ It drains into internal jugular vein

4. Select the **incorrect statement** regarding anterior jugular vein:

- Ⓐ It is formed below the chin in submental region
- Ⓑ It runs about 1 cm lateral to anterior midline of the neck
- Ⓒ It is joined with its counterpart of opposite side by jugular venous arch
- Ⓓ It drains into subclavian vein

5. All of the following are derivatives of deep cervical fascia **except:**

- Ⓐ Pretracheal fascia
- Ⓑ Prevertebral fascia
- Ⓒ Stylomandibular ligament
- Ⓓ Sphenomandibular ligament

6. Superficial lymph nodes of neck consist of all of the following groups of lymph nodes **except:**

- ❑(a) Submental
  - ❑(b) Submandibular
  - ❑(c) Retroauricular
  - ❑(d) Retropharyngeal
7. ‘ **Suprasternal space of Burns** ’ contains all of the following structures **except**:
- ❑(a) Jugular venous arch
  - ❑(b) Interclavicular ligament
  - ❑(c) Terminal ends of external jugular veins
  - ❑(d) Sternal heads of sternocleidomastoid muscles
8. All of the following are contents of carotid sheath **except**:
- ❑(a) Internal carotid artery
  - ❑(b) External carotid artery
  - ❑(c) Internal jugular vein
  - ❑(d) Vagus nerve
9. Select **incorrect statement** about the carotid sheath:
- ❑(a) It extends from base of skull to the clavicle
  - ❑(b) Ansa cervicalis is embedded in its anterior wall
  - ❑(c) It is ill defined over the internal jugular vein
  - ❑(d) The cervical sympathetic chain is posterior to it
10. Select **incorrect statement** regarding cold abscess due to tubercular caries of cervical vertebrae:
- ❑(a) Produces paramedian bulge in posterior pharyngeal wall
  - ❑(b) Produces median bulge in posterior pharyngeal wall
  - ❑(c) It may extend into posterior triangle of the neck
  - ❑(d) It may extend into axilla and arm.

## Answers

1. **b** , 2. **a** , 3. **d** , 4. **d** , 5. **d** , 6. **d** , 7. **c** , 8. **b** , 9. **a** , 10. **a**

## Chapter 5

1. All of the following muscles form floor of posterior triangle **except**:
  - ❑(a) Splenius capitis
  - ❑(b) Levator scapulae
  - ❑(c) Scalenus medius
  - ❑(d) Scalenus anterior
2. All of the following structures lie deep to fascial carpet of posterior triangle **except**

- ⌘(a) Trunks of brachial plexus
  - ⌘(b) Spinal accessory nerve
  - ⌘(c) Occipital artery
  - ⌘(d) Third part of subclavian artery
3. Select **incorrect statement** regarding spinal accessory nerve:
- ⌘(a) It emerges in posterior triangle by piercing the posterior border of sternocleidomastoid
  - ⌘(b) It is related to lymph nodes belonging to upper deep cervical lymph nodes
  - ⌘(c) It runs parallel to the fibres of scalenus medius
  - ⌘(d) It supplies sternocleidomastoid and trapezius muscles
4. All of the following nerves arise from cervical part of the brachial plexus **except**:
- ⌘(a) Dorsal scapular nerve
  - ⌘(b) Nerve to serratus anterior
  - ⌘(c) Musculocutaneous nerve
  - ⌘(d) Suprascapular nerve
5. Select **incorrect statement** regarding the sternocleidomastoid muscle:
- ⌘(a) It tilts the head to the same side
  - ⌘(b) It overlaps the carotid sheath
  - ⌘(c) It is supplied by cranial root of accessory nerve
  - ⌘(d) It is crossed superficially by external Jugular vein
6. The sternocleidomastoid muscle is crossed superficially by all of the following structures **except**:
- ⌘(a) Lesser occipital nerve
  - ⌘(b) Great auricular nerve
  - ⌘(c) External jugular vein
  - ⌘(d) Transverse cervical nerve
7. Which of the following lymph nodes are termed **Virchow's lymph nodes**:
- ⌘(a) Left infraclavicular
  - ⌘(b) Left supraclavicular
  - ⌘(c) Right infraclavicular
  - ⌘(d) Right supraclavicular
8. All of the following structures pierce the roof of posterior triangle **except**:
- ⌘(a) Anterior jugular vein

- ❑b) External jugular vein
- ❑c) Supraclavicular nerves
- ❑d) Great auricular nerve

## Answers

1. **d** , 2. **b** , 3. **c** , 4. **c** , 5. **c** , 6. **a** , 7. **b** , 8. **a**

## Chapter 6

1. Select **incorrect statement** about the mental triangle:
  - ❑a) It is located in the anterior median region of the neck
  - ❑b) Its floor is formed by the oral diaphragm
  - ❑c) It is bounded on either side by the posterior belly of digastric muscle
  - ❑d) Its base is formed by the body of hyoid bone
2. All of the following structures form the boundaries of digastric triangle **except**:
  - ❑a) Posterior belly of digastric muscle
  - ❑b) Anterior belly of digastric muscle
  - ❑c) Superior belly of omohyoid muscle
  - ❑d) Base of the mandible
3. All of the following structures pass between external and internal carotid arteries **except**:
  - ❑a) Stylopharyngeus muscle
  - ❑b) Superior laryngeal nerve
  - ❑c) Glossopharyngeal nerve
  - ❑d) Pharyngeal branch of vagus nerve
4. Select **incorrect statement** regarding the carotid sinus:
  - ❑a) It is fusiform dilatation at the beginning of the internal carotid artery
  - ❑b) It is innervated by vagus nerve
  - ❑c) It is innervated by glossopharyngeal nerve
  - ❑d) It acts as a pressure receptor
5. All of the following arteries are present in the carotid triangle **except**:
  - ❑a) Ascending pharyngeal artery
  - ❑b) Lingual artery
  - ❑c) Sublingual artery
  - ❑d) Facial artery
6. All of the following statements are true about the ansa cervicalis

**except:**

- ❑(a) It is present in the region of carotid triangle
- ❑(b) It is formed by the ventral rami of C1, C2, and C3 spinal nerves
- ❑(c) It supplies all the infrahyoid muscles
- ❑(d) It is embedded in anterior wall of the carotid sheath

7. 'Strap' muscles of the neck include all of the following muscles

**except:**

- ❑(a) Sternocleidomastoid
- ❑(b) Sternothyroid
- ❑(c) Sternohyoid
- ❑(d) Thyrohyoid

8. Which of the following strap muscles of the neck can elevate the larynx if hyoid is fixed:

- ❑(a) Sternohyoid
- ❑(b) Omohyoid
- ❑(c) Sternothyroid
- ❑(d) Thyrohyoid

9. The thyrohyoid muscle is supplied by:

- ❑(a) Superior root of ansa cervicalis
- ❑(b) Inferior root of ansa cervicalis
- ❑(c) Ventral ramus of first cervical nerve through hypoglossal nerve
- ❑(d) Ventral ramus of first cervical nerve through superior laryngeal nerve

10. Hypoglossal nerve crosses superficial to all of the following arteries

**except:**

- ❑(a) Internal carotid artery
- ❑(b) External carotid artery
- ❑(c) Facial artery
- ❑(d) Loop of lingual artery.

## Answers

1. **c** , 2. **c** , 3. **b** , 4. **b** , 5. **c** , 6. **c** , 7. **a** , 8. **d** , 9. **c** , 10. **c**

## Chapter 7

1. All of the following nerves provide cutaneous innervation on the back of neck **except:**

- ❑(a) Lesser occipital nerve
- ❑(b) Greater occipital nerve

- ⌘c) Third occipital nerve
  - ⌘d) Cutaneous branches of C4 and C5
2. Regarding ligamentum nuchae, all of the following statements are correct **except**:
- ⌘a) Its free posterior border extends from external occipital protuberance to the spine of the cervical vertebra
  - ⌘b) It is better developed and more elastic in humans than in quadrupeds
  - ⌘c) It forms the septum between the muscles of the two sides of the back of the neck
  - ⌘d) It consists of a number of elastic fibres
3. From the following statements select the **incorrect statement** about the trapezius muscle:
- ⌘a) It arises from lateral third of the superior nuchal line
  - ⌘b) Its lower part is inserted into the tubercle on the spine of scapula
  - ⌘c) It is supplied by the spinal accessory nerve
  - ⌘d) Its upper fibres help in shrugging the shoulder
4. The contents of suboccipital triangle includes all **except**:
- ⌘a) Third part of vertebral artery
  - ⌘b) Suboccipital nerve
  - ⌘c) Occipital artery
  - ⌘d) Suboccipital venous plexus
5. All of the following statements regarding suboccipital triangle are correct **except**:
- ⌘a) Its roof is covered by semispinalis capitis and longissimus capitis
  - ⌘b) Its floor is formed by anterior arch of the atlas
  - ⌘c) It is bounded inferiorly by oblique capitis inferior
  - ⌘d) It is bounded superolaterally by obliquus capitis superior
6. The dorsal ramus first cervical nerve supplies all of the following muscles **except**:
- ⌘a) Rectus capitis posterior major
  - ⌘b) Rectus capitis posterior minor
  - ⌘c) Semispinalis capitis
  - ⌘d) Splenius capitis
7. The joints of neck include all of the following varieties **except**:
- ⌘a) Symphyses

- ⌘(b) Syndesmoses
- ⌘(c) Sutures
- ⌘(d) Synovium

8. Select the **incorrect statement** about the intervertebral disc:

- ⌘(a) Its outer part is made up of annulus fibrosus
- ⌘(b) Its inner part is made up of nucleus pulposus
- ⌘(c) It along with hyaline cartilages forms the intervertebral symphysis
- ⌘(d) It is thicker posteriorly in the cervical region

9. All of the following are **true statements** about the ligamentum nuchae **except**:

- ⌘(a) Its posterior border extends from external occipital protuberance to the spine of C7
- ⌘(b) It is bilaminar in nature
- ⌘(c) It is predominantly made up fibroelastic tissue
- ⌘(d) It is weak in quadrupeds

10. Select the **incorrect statement** about the atlanto-occipital joints:

- ⌘(a) They are synovial joints of ellipsoid variety
- ⌘(b) They are two in number
- ⌘(c) They are responsible for rotatory movements of the head
- ⌘(d) They are supplied by first cervical nerve

11. Select the **incorrect statement** about the median atlantoaxial joint:

- ⌘(a) It is a synovial joint of pivot variety
- ⌘(b) It has two joint cavities
- ⌘(c) It is formed between the dens of axis and osseo- ligamentous ring formed by the anterior arch and transverse ligament of atlas
- ⌘(d) It is responsible for 'yes movement' of head

12. Select the **incorrect statement** about the atlantoaxial joints:

- ⌘(a) They are 3 in number
- ⌘(b) Lateral atlantoaxial joints are synovial joints of plane variety
- ⌘(c) Median atlantoaxial joint is a synovial joint of pivot type
- ⌘(d) The movements at all the atlantoaxial joints do not occur simultaneously

13. Which of the following structures represents the remnant of notochord?

- ⌘(a) Alar ligaments of dens
- ⌘(b) Membrana tectoria
- ⌘(c) Apical ligament of dens

❑d) Upper longitudinal band of transverse ligament of atlas

## Answers

1. **a** , 2. **b** , 3. **a** , 4. **c** , 5. **b** , 6. **d** , 7. **c** , 8. **d** , 9. **d** , 10. **c** , 11. **d** , 12. **d** , 13. **c**

## Chapter 8

1. The parotid gland develops from:
  - ❑a) Ectoderm
  - ❑b) Endoderm
  - ❑c) Mesoderm
  - ❑d) None of the above
2. Select the **correct statement** about the parotid gland:
  - ❑a) It is located in the retromandibular fossa
  - ❑b) It is composed mainly of mucous acini
  - ❑c) It gets its secretomotor supply through facial nerve
  - ❑d) It is devoid of capsule
3. All of the following structures emerge underneath anterior border of the parotid gland **except**:
  - ❑a) Zygomatic branch of the facial nerve
  - ❑b) Parotid duct
  - ❑c) Retromandibular vein
  - ❑d) Transverse facial vessels
4. All of the following structures lie within the parotid gland **except**:
  - ❑a) Facial nerve
  - ❑b) Retromandibular vein
  - ❑c) Internal carotid artery
  - ❑d) External carotid artery
5. All of the following structures are pierced by the parotid duct **except**:
  - ❑a) Buccal pad of fat
  - ❑b) Buccinator muscle
  - ❑c) Pharyngobasilar fascia
  - ❑d) Buccopharyngeal fascia
6. Select the **incorrect statement** about the parotid duct:
  - ❑a) It is 5 cm long
  - ❑b) It is also called Wharton duct
  - ❑c) It emerges from the middle of anterior border of the parotid gland
  - ❑d) It turns inwards at anterior border of masseter

7. The parotid duct opens in the vestibule of mouth opposite the crown of which of the following tooth:
- Ⓐ Upper first molar
  - Ⓑ Upper second molar
  - Ⓒ Upper third molar
  - Ⓓ Upper first premolar
8. The secretory function of parotid gland is likely to be affected by:
- Ⓐ Severe or prolonged middle ear infection
  - Ⓑ Facial nerve palsy
  - Ⓒ Severing of the glossopharyngeal nerve as it winds around the stylopharyngeus muscle
  - Ⓓ None of the above
9. The deep lamina of parotid capsule thickens to form:
- Ⓐ Sphenomandibular ligament
  - Ⓑ Stylohyoid ligament
  - Ⓒ Stylomandibular ligament
  - Ⓓ All of the above
10. The secretomotor fibres to the parotid gland are conveyed through the:
- Ⓐ Greater superficial petrosal nerve
  - Ⓑ Auriculotemporal nerve
  - Ⓒ Chorda tympani nerve
  - Ⓓ Pharyngeal branch of the glossopharyngeal nerve
11. Select the **incorrect statement** about the parotid capsule:
- Ⓐ It is derived from investing layer of deep cervical fascia
  - Ⓑ It consists of superficial and deep laminae
  - Ⓒ Its superficial lamina is thick and unyielding
  - Ⓓ It is derived from prevertebral layer of deep cervical fascia
12. Bony boundaries of the parotid bed are formed by all **except**:
- Ⓐ Posterior border of the ramus of mandible
  - Ⓑ Mastoid process
  - Ⓒ Styloid process
  - Ⓓ Internal acoustic meatus
13. 'Mixed parotid tumour' commonly involves:
- Ⓐ Superficial part of the parotid gland including facial nerve
  - Ⓑ Superficial part of the parotid gland without involving facial nerve
  - Ⓒ Deep part of the parotid gland including facial nerve

❑d) Deep part of the parotid gland without involving facial nerve

## Answers

1. **a** , 2. **a** , 3. **c** , 4. **c** , 5. **c** , 6. **b** , 7. **b** , 8. **a** , 9. **c** , 10. **b** , 11. **d** , 12. **d** , 13. **b**

## Chapter 9

1. Regarding digastric muscle, all of the following statement are true **except:**
  - ❑a) Its posterior belly is bipinnate and is supplied by the facial nerve
  - ❑b) Its anterior belly is unipinnate and is supplied by the mandibular nerve
  - ❑c) Its intermedial tendon is anchored to hyoid bone of a fascial sling
  - ❑d) It helps to elevate the mandible
2. The superficial relation of hyoglossus muscle includes all **except:**
  - ❑a) Lingual nerve
  - ❑b) Lingual artery
  - ❑c) Hypoglossal nerve
  - ❑d) Deep part of sublingual gland
3. All of the following structures pass deep to posterior border of hyoglossus muscle **except:**
  - ❑a) Glossopharyngeal nerve
  - ❑b) Stylohyoid muscle
  - ❑c) Stylohyoid ligament
  - ❑d) Lingual artery
4. All of the following statements regarding genioglossus muscle are correct **except:**
  - ❑a) It arises from superior genial tubercle
  - ❑b) It is called 'safety-muscle' of the tongue
  - ❑c) It along with its counterpart of opposite side protrudes the tongue
  - ❑d) It alone protrudes the tongue to the same side
5. The swellings of submandibular gland are bimanually palpable because:
  - ❑a) It lies superficial to mylohyoid muscle outside the oral cavity
  - ❑b) Its deep part lies in the oral cavity and superficial part outside the oral cavity
  - ❑c) It is wedged between the mandible and mylohyoid muscle

- ☐(d) It is immediately deep to the oral mucosa
6. Select the **incorrect statement** about the submandibular gland:
- ☐(a) It develops from endoderm
  - ☐(b) It consists of superficial and deep parts
  - ☐(c) Its duct opens into the vestibule of the oral cavity
  - ☐(d) It is grooved by the facial artery
7. Which of the following nerves crosses the duct of the submandibular gland?
- ☐(a) Glossopharyngeal nerve
  - ☐(b) Hypoglossal nerve
  - ☐(c) Lingual nerve
  - ☐(d) Chorda tympani nerve
8. Select the **correct statement** about the sublingual gland:
- ☐(a) It is drained by a single duct
  - ☐(b) It lies inside the oral cavity between mucous membrane and genioglossus muscle
  - ☐(c) It receives postganglionic secretomotor fibres from otic ganglion
  - ☐(d) It is composed mainly of serous acini
9. The postganglionic secretomotor fibres to sublingual gland pass through which of the following nerves:
- ☐(a) Lingual nerve
  - ☐(b) Chorda tympani nerve
  - ☐(c) Glossopharyngeal nerve
  - ☐(d) Hypoglossal nerve
10. A **correct statement** about the submandibular ganglion is:
- ☐(a) It is functionally related to the facial nerve
  - ☐(b) It is situated on the inner surface of the hyoglossus muscle
  - ☐(c) It lies above the lingual nerve
  - ☐(d) It supplies preganglionic parasympathetic fibres to submandibular and sublingual salivary glands

## Answers

1. **d** , 2. **b** , 3. **b** , 4. **d** , 5. **b** , 6. **c** , 7. **c** , 8. **b** , 9. **a** , 10. **a**

## Chapter 10

1. Select the **incorrect statement** about the infratemporal fossa:
- ☐(a) It is located deep to the ramus of mandible
  - ☐(b) It contains medial and lateral pterygoid muscles

- ⌘(c) It communicates with pterygopalatine fossa
  - ⌘(d) It contains submandibular parasympathetic ganglion
2. All of the following structures occupy the infratemporal fossa **except:**
- ⌘(a) Mandibular nerve
  - ⌘(b) Chorda tympani nerve
  - ⌘(c) Pterygoid venous plexus
  - ⌘(d) Masseter muscle
3. All of the following structures lie deep to lateral pterygoid muscle **except:**
- ⌘(a) Middle meningeal artery
  - ⌘(b) Mandibular nerve
  - ⌘(c) Superficial head of medial pterygoid
  - ⌘(d) Sphenomandibular ligament
4. All of the following nerves derived from anterior division of the mandibular nerve are motor **except:**
- ⌘(a) Masseteric nerve
  - ⌘(b) Buccal nerve
  - ⌘(c) Nerve to lateral pterygoid
  - ⌘(d) Deep temporal nerves
5. All of the following arteries arise from the first part of maxillary artery **except:**
- ⌘(a) Middle meningeal artery
  - ⌘(b) Posterior superior alveolar artery
  - ⌘(c) Inferior alveolar artery
  - ⌘(d) Accessory middle meningeal artery
6. Select the **incorrect statement** about the otic ganglion:
- ⌘(a) It is functionally related to mandibular nerve
  - ⌘(b) It is topographically related to mandibular nerve
  - ⌘(c) It is 2–3 mm in size
  - ⌘(d) It is located lateral to tensor palati muscle
7. Nerve to medial pterygoid supplies all of the following muscles **except:**
- ⌘(a) Tensor palati
  - ⌘(b) Medial pterygoid
  - ⌘(c) Lateral pterygoid
  - ⌘(d) Tensor tympani
8. Select the **incorrect statement** about the temporomandibular joint:
- ⌘(a) It is synovial joint of condylar variety

- ⌘(b) Its cavity is divided into two compartments by an intra-articular disc
  - ⌘(c) Its articular surfaces are covered by hyaline cartilage
  - ⌘(d) It is innervated by auriculotemporal and masseteric nerves
9. Which of the following muscles opens the mouth:
- ⌘(a) Temporalis
  - ⌘(b) Lateral pterygoid
  - ⌘(c) Medial pterygoid
  - ⌘(d) Posteriorly
10. The temporomandibular joint is commonly dislocated:
- ⌘(a) Medially
  - ⌘(b) Laterally
  - ⌘(c) Anteriorly
  - ⌘(d) Posteriorly

### Answers

1. **d** , 2. **d** , 3. **c** , 4. **b** , 5. **b** , 6. **a** , 7. **c** , 8. **c** , 9. **b** , 10. **c**

## Chapter 11

1. The **true statement** about the thyroid gland is:
  - ⌘(a) It develops from the thyroglossal duct
  - ⌘(b) It lies opposite to C3–C7 cervical vertebrae
  - ⌘(c) Its isthmus lies opposite cricoid cartilage
  - ⌘(d) It is the least vascular endocrine gland in the body
2. Select the **incorrect statement** regarding the isthmus of thyroid gland:
  - ⌘(a) It lies in front of the 2nd, 3rd, and 4th tracheal rings
  - ⌘(b) It connects upper parts of the two lateral lobes of thyroid gland
  - ⌘(c) Its anterior surface is related to sternothyroid and sternohyoid muscles
  - ⌘(d) Anastomosis between the anterior branches of superior thyroid arteries lies along its upper border
3. The inferior thyroid artery is a branch of:
  - ⌘(a) External carotid artery
  - ⌘(b) Internal carotid artery
  - ⌘(c) Thyrocervical trunk
  - ⌘(d) Brachiocephalic trunk
4. The suspensory ligaments of Berry are derived from:

- Ⓐ Prevertebral fascia
  - Ⓑ Pretracheal fascia
  - Ⓒ Condensation of fibrous stroma of thyroid gland
  - Ⓓ Investing layer of deep cervical fascia
5. The thyroid venous plexus lies:
- Ⓐ Between true and false capsules of thyroid gland
  - Ⓑ Deep to true capsule of thyroid gland
  - Ⓒ Outside the false capsule of the gland
  - Ⓓ Within the substance of the gland
6. The **true statement** regarding the inferior thyroid veins is that they:
- Ⓐ Arise from the inferior poles of the thyroid lobes
  - Ⓑ Arise from the isthmus of thyroid gland
  - Ⓒ Drain into the internal jugular vein
  - Ⓓ Drain into the right brachiocephalic vein
7. The medial surface of the thyroid lobe is related to all the following structures **except**:
- Ⓐ Trachea
  - Ⓑ Oesophagus
  - Ⓒ Carotid sheath
  - Ⓓ Thyropharyngeus muscle
8. Select the **true statement** about the inferior parathyroid gland:
- Ⓐ It develops from the third pharyngeal pouch
  - Ⓑ It develops from the fourth pharyngeal pouch
  - Ⓒ It is more constant in position as compared to the superior parathyroid gland
  - Ⓓ It is closely related to external laryngeal nerve
9. Select the **true statement** about cervical part of trachea:
- Ⓐ It extends from lower border of cricoid cartilage to the superior border of manubrium sterni
  - Ⓑ It is related to oesophagus on its anterior aspect
  - Ⓒ It is related on each side to the external laryngeal nerve
  - Ⓓ It is related on its posterior aspect to the isthmus of the thyroid gland
10. Select the **incorrect statement** about the cervical part of oesophagus:
- Ⓐ It extends from the lower border of the cricoid cartilage to the superior border of the manubrium sterni
  - Ⓑ Its lumen normally remains collapsed, except during swallowing
  - Ⓒ It projects from behind the trachea on the left side

❑d) It is supplied by the superior thyroid arteries

## Answers

1. **a** , 2. **b** , 3. **c** , 4. **b** , 5. **b** , 6. **b** , 7. **c** , 8. **a** , 9. **a** , 10. **d**

## Chapter 12

1. The prevertebral muscles include all of the following muscles **except**:
  - ❑a) Longus colli
  - ❑b) Longus capitis
  - ❑c) Longissimus capitis
  - ❑d) Rectus capitis lateralis
2. The lateral vertebral group of muscles does not include:
  - ❑a) Scalenus anterior
  - ❑b) Scalenus medius
  - ❑c) Scalenus posterior
  - ❑d) Levator scapulae
3. The key muscle at the root of neck is:
  - ❑a) Scalenus anterior
  - ❑b) Scalenus medius
  - ❑c) Scalenus posterior
  - ❑d) Longus cervicis
4. Select the **incorrect statement** about the scalenus anterior muscle:
  - ❑a) Arises from anterior tubercles of the transverse processes of C3 to C6 vertebrae
  - ❑b) Is inserted on the scalene tubercle of first rib
  - ❑c) Lies superficial to prevertebral fascia
  - ❑d) Forms the lateral boundary of triangle of vertebral artery
5. All of the following structures form the boundary of *scalenovertbral* triangle **except**:
  - ❑a) Lower oblique part of longus colli
  - ❑b) Medial border of scalenus anterior
  - ❑c) Transverse process of C6 vertebra
  - ❑d) First rib
6. All of the following structures cross in front of the neck of first rib **except**:
  - ❑a) Sympathetic chain
  - ❑b) First posterior intercostal vein
  - ❑c) First posterior intercostal artery

- Ⓔd) First thoracic spinal nerve
7. Select the **incorrect statement** about the cervical plexus:
- Ⓔa) It is formed of the ventral rami of C1 to C4 cervical spinal nerves
  - Ⓔb) It is called plexus of loops
  - Ⓔc) It lies superficial to prevertebral fascia
  - Ⓔd) Its superficial branches are cutaneous in nature
8. All of the following statement about the cervical sympathetic trunk are true **except**:
- Ⓔa) It lies in front of the transverse processes of cervical vertebrae and neck of the first rib
  - Ⓔb) It receives the preganglionic fibre through the white rami communicates of cervical spinal nerves
  - Ⓔc) It possesses three ganglia
  - Ⓔd) Its injury leads to Horner's syndrome
9. Select the **incorrect statement** about the inferior cervical sympathetic ganglion:
- Ⓔa) It is formed by the fusion of 7th and 8th primitive cervical sympathetic ganglia
  - Ⓔb) It lies in front of transverse process of C6 vertebra
  - Ⓔc) It is also called stellate ganglion
  - Ⓔd) It is connected to middle cervical sympathetic ganglia by ansa cervicalis.

## Answers

1. **c** , 2. **d** , 3. **a** , 4. **c** , 5. **d** , 6. **c** , 7. **c** , 8. **b** , 9. **b**

## Chapter 13

1. All of the following glands pour their secretion into the vestibule of mouth **except**:
- Ⓔa) Parotid glands
  - Ⓔb) Sublingual glands
  - Ⓔc) Labial and buccal mucous glands
  - Ⓔd) Molar glands
2. Select the **incorrect statement** about the lips:
- Ⓔa) They bound the orifice of mouth
  - Ⓔb) They are lined externally by the skin and internally by the mucous membrane
  - Ⓔc) Their red portions are called vermillion zones

- ⌘(d) Lymphatics from lateral part of lower lip drain into submental lymph nodes
3. Which of the following types of teeth are not found in deciduous dentition?
- ⌘(a) Incisors
  - ⌘(b) Canines
  - ⌘(c) Premolars
  - ⌘(d) Molars
4. All of the following tissues develop from neural crest cells **except**:
- ⌘(a) Enamel
  - ⌘(b) Dentin
  - ⌘(c) Dental pulp
  - ⌘(d) Cementum
5. Select the **incorrect statement** above the gums:
- ⌘(a) They are composed of fibrous tissue covered with a vascular mucous membrane
  - ⌘(b) They envelop the roots of teeth
  - ⌘(c) Fibrous tissue of gum becomes continuous with the periodontal membrane
  - ⌘(d) Lymphatic from gums drains into submental and submandibular lymph nodes
6. Select the **incorrect statement** about the root of the tongue:
- ⌘(a) It is the part of tongue that rests on the floor of the mouth
  - ⌘(b) It is attached by the extrinsic muscles to the mandible and hyoid bone
  - ⌘(c) The nerves and vessels of tongue enter or leave through the root
  - ⌘(d) It is attached by the intrinsic muscles to the mandible and hyoid bone
7. All the muscles of the tongue are supplied by the hypoglossal nerve **except**:
- ⌘(a) Palatoglossus
  - ⌘(b) Styloglossus
  - ⌘(c) Hyoglossus
  - ⌘(d) Genioglossus
8. All of the following cranial nerves carry taste sensations from tongue **except**:
- ⌘(a) Facial nerve
  - ⌘(b) Glossopharyngeal nerve

- ⌘(c) Vagus nerve
- ⌘(d) Hypoglossal nerve
- 9. The most abundant papillae on the dorsum of tongue are:
  - ⌘(a) Filiform
  - ⌘(b) Fungiform
  - ⌘(c) Foliate
  - ⌘(d) Vallate
- 10. The pain from tongue is referred to the ear through:
  - ⌘(a) Mandibular nerve
  - ⌘(b) Facial nerve
  - ⌘(c) Glossopharyngeal nerve
  - ⌘(d) Hypoglossal nerve

### Answers

1. **b** , 2. **d** , 3. **c** , 4. **a** , 5. **b** , 6. **d** , 7. **a** , 8. **d** , 9. **a** , 10. **a**

## Chapter 14

1. Select the **incorrect statement** about the pharynx:
  - ⌘(a) It extends from base of skull to the lower border of C6 vertebra
  - ⌘(b) It lies behind the nasal, oral, and laryngeal cavities
  - ⌘(c) It is about 25 cm long
  - ⌘(d) It is a common channel for both deglutition and respiration
2. The pharyngeal wall consists of all the following **except**:
  - ⌘(a) Mucous membrane
  - ⌘(b) Pharyngobasilar fascia
  - ⌘(c) Buccopharyngeal fascia
  - ⌘(d) Prevertebral fascia
3. The weakest region in the posterior pharyngeal wall is between:
  - ⌘(a) Superior and middle constrictors
  - ⌘(b) Middle and inferior constrictors
  - ⌘(c) Thyropharyngeus and cricopharyngeus
  - ⌘(d) Inferior constrictor and oesophagus
4. All of the following are features of nasopharynx **except**:
  - ⌘(a) Pharyngeal tonsil
  - ⌘(b) Tubal tonsil
  - ⌘(c) Pharyngeal recess
  - ⌘(d) Piriform recess
5. The Passavant's ridge is formed by:

- Ⓐ Salpingopharyngeus
  - Ⓑ Stylopharyngeus
  - Ⓒ Palatopharyngeus
  - Ⓓ Thyropharyngeus
6. All of the following structures pass between the base of the skull and upper border of superior constrictor **except**:
- Ⓐ Auditory tube
  - Ⓑ Levator palati muscle
  - Ⓒ Tensor palati muscle
  - Ⓓ Ascending palatine artery
7. Motor nerve supply of pharyngeal muscles is derived from:
- Ⓐ Vagoaccessory complex
  - Ⓑ Glossopharyngeal nerve
  - Ⓒ External laryngeal nerve
  - Ⓓ All of the above
8. Inferior constrictor of pharynx is supplied by all of the following nerves **except**:
- Ⓐ Pharyngeal plexus
  - Ⓑ Glossopharyngeal nerve
  - Ⓒ External laryngeal nerve
  - Ⓓ Recurrent laryngeal nerve
9. Select the **incorrect statement** about the palatine tonsil:
- Ⓐ It is located in the lateral wall of oropharynx
  - Ⓑ Its medial surface is lined by keratinized stratified squamous epithelium
  - Ⓒ Its lateral surface is covered by a capsule
  - Ⓓ Its apex extends upwards into the soft palate
10. Tonsillar-bed is formed by all of the following structures **except**:
- Ⓐ Pharyngobasilar fascia
  - Ⓑ Stylopharyngeus
  - Ⓒ Superior constrictor
  - Ⓓ Styloglossus
11. Select the **incorrect statement** about the pharyngo- tympanic tube:
- Ⓐ It is about 36 mm long
  - Ⓑ Its tympanic end is wider than its pharyngeal end
  - Ⓒ It is lined by pseudostratified ciliated columnar epithelium
  - Ⓓ It maintains the equilibrium of air pressure on each side of tympanic membrane

12. Median cleft of upper lip occurs if:

- Ⓐ Maxillary process fails to fuse with frontonasal process
- Ⓑ Both maxillary processes do not fuse with philtrum
- Ⓒ Philtrum fails to develop from frontonasal process
- Ⓓ Mandibular processes fail to fuse with each other

## Answers

1. **c** , 2. **d** , 3. **c** , 4. **d** , 5. **c** , 6. **c** , 7. **d** , 8. **b** , 9. **b** , 10. **b** , 11. **b** , 12. **c**

## Chapter 15

1. Which of the following cartilages completely encircle the laryngeal cavity?

- Ⓐ Thyroid
- Ⓑ Cricoid
- Ⓒ Epiglottis
- Ⓓ Arytenoid

2. All of the following cartilages of larynx are composed of hyaline cartilage **except**:

- Ⓐ Epiglottis
- Ⓑ Thyroid
- Ⓒ Cricoid
- Ⓓ Arytenoid (basal part)

3. All of the following structures form the boundaries of laryngeal inlet **except**:

- Ⓐ Epiglottis
- Ⓑ Interarytenoid fold
- Ⓒ Lamina of thyroid cartilage
- Ⓓ Aryepiglottic fold

4. Select the **incorrect statement** about the cricothyroid muscle:

- Ⓐ It is placed externally on the laryngeal wall
- Ⓑ It tenses the vocal cord
- Ⓒ It is supplied by the internal laryngeal nerve
- Ⓓ It causes adduction of vocal cord

5. Select the **incorrect statement** about the vocal cord:

- Ⓐ It is made up of vocal ligament
- Ⓑ It is devoid of mucous glands
- Ⓒ It extends between arytenoid and epiglottis
- Ⓓ It is lined by stratified squamous epithelium

6. The space between the right and left vocal fold is called:
- ❑(a) Vestibule
  - ❑(b) Rima vestibuli
  - ❑(c) Ventricle
  - ❑(d) Rima glottidis
7. All of the following muscles adduct the vocal folds **except**:
- ❑(a) Lateral cricoarytenoid
  - ❑(b) Posterior cricoarytenoid
  - ❑(c) Thyroarytenoid
  - ❑(d) Interarytenoid
8. Select the **correct statement** about the cricothyroid joint:
- ❑(a) It is a synovial joint
  - ❑(b) It is a primary cartilaginous joint
  - ❑(c) It is a secondary cartilaginous joint
  - ❑(d) It is a fibrous joint
9. The vocal folds lie in cadaveric position if:
- ❑(a) Internal laryngeal nerves of both sides are involved
  - ❑(b) External laryngeal nerves of both sides are involved
  - ❑(c) External laryngeal nerve of right side and internal laryngeal nerve of left side are involved
  - ❑(d) External and internal laryngeal nerves of both sides are involved
10. All of the following areas are covered by stratified squamous epithelium **except**:
- ❑(a) Anterior surface of epiglottis
  - ❑(b) Lower half of the posterior surface of epiglottis
  - ❑(c) Upper parts of aryepiglottic folds
  - ❑(d) Vocal folds

## Answers

1. **b** , 2. **a** , 3. **c** , 4. **c** , 5. **c** , 6. **d** , 7. **b** , 8. **a** , 9. **d** , 10. **b**

## Chapter 16

1. Which of the following statements is not correct regarding the subclavian arteries?
- ❑(a) They are the principal source of arterial supply to the upper limbs
  - ❑(b) Right subclavian artery arises from brachiocephalic trunk
  - ❑(c) Left subclavian artery arises from the arch of aorta

- ❑d) Both the subclavian arteries have thoracic as well as cervical part
2. All of the following arteries arise from the first part of subclavian artery **except:**
- ❑a) Thyrocervical trunk
  - ❑b) Dorsal scapular artery
  - ❑c) Internal mammary artery
  - ❑d) Vertebral artery
3. Vertebral artery does not pass through the foramen transversarium of:
- ❑a) First cervical vertebra
  - ❑b) Second cervical vertebra
  - ❑c) Sixth cervical vertebra
  - ❑d) Seventh cervical vertebra
4. All of the following arteries arise from thyrocervical trunk **except:**
- ❑a) Inferior thyroid artery
  - ❑b) Suprascapular artery
  - ❑c) Dorsal scapular artery
  - ❑d) Superficial cervical artery
5. The subclavian artery is divided into three parts by:
- ❑a) Scalenus posterior muscle
  - ❑b) Scalenus medius muscle
  - ❑c) Scalenus anterior muscle
  - ❑d) Scalenus minimus muscle
6. Select the **true statement** about the vertebral artery:
- ❑a) It is the smallest branch of the subclavian artery
  - ❑b) It traverses foramen transversaria of all cervical vertebrae except that of C1
  - ❑c) It does not give any branch in the neck
  - ❑d) It winds backwards around the lateral mass of the first cervical vertebra.
7. Select the **incorrect statement** about the carotid sinus:
- ❑a) It is a dilatation at the beginning of internal carotid artery
  - ❑b) It acts as a chemoreceptor
  - ❑c) It is innervated by glossopharyngeal nerve
  - ❑d) It regulates the blood pressure in the cerebral arteries.
8. The cervical part of facial artery gives all of the following branches **except:**
- ❑a) Inferior alveolar artery
  - ❑b) Tonsillar artery

- ⌘(c) Glandular branches to submandibular gland
  - ⌘(d) Submental artery
- 9. The cerebral part of internal carotid artery gives all of the following branches **except** :
  - ⌘(a) Anterior cerebral artery
  - ⌘(b) Posterior communicating artery
  - ⌘(c) Posterior choroidal artery
  - ⌘(d) Middle cerebral artery
- 10. Select the **incorrect statement** about the internal jugular vein:
  - ⌘(a) It begins as the direct continuation of sigmoid sinus
  - ⌘(b) It presents two dilatations
  - ⌘(c) It is crossed by two muscles on its superficial aspect
  - ⌘(d) Its lower part lies in the greater supraclavicular fossa

### Answers

1. **d** , 2. **b** , 3. **d** , 4. **c** , 5. **c** , 6. **d** , 7. **b** , 8. **a** , 9. **c** , 10. **d**

## Chapter 17

1. The olfactory receptor cells are:
  - ⌘(a) Unipolar neurons
  - ⌘(b) Bipolar neurons
  - ⌘(c) Pseudounipolar neurons
  - ⌘(d) Multipolar neurons
2. The nasolacrimal duct opens into:
  - ⌘(a) Middle meatus of the nose
  - ⌘(b) Superior meatus of the nose
  - ⌘(c) Inferior meatus of the nose
  - ⌘(d) Vestibule of the nose
3. All of the following structures form nasal septum **except**:
  - ⌘(a) Perpendicular plate of ethmoid
  - ⌘(b) Perpendicular plate of palatine
  - ⌘(c) Vomer
  - ⌘(d) Septal cartilage
4. All are parts of ethmoid bone **except**:
  - ⌘(a) Superior nasal concha
  - ⌘(b) Middle nasal concha
  - ⌘(c) Inferior nasal concha
  - ⌘(d) Cribriform plate

5. The chief artery supplying the nasal mucosa is:
- Ⓐ Greater palatine
  - Ⓑ Sphenopalatine
  - Ⓒ Anterior ethmoidal
  - Ⓓ Posterior ethmoidal
6. All arteries take part in the formation of Kiesselbach's plexus **except**:
- Ⓐ Septal branch of sphenopalatine
  - Ⓑ Septal branch of greater palatine
  - Ⓒ Septal branch of posterior ethmoidal
  - Ⓓ Septal branch of anterior ethmoidal
7. The chief nerve providing innervation to the nasal mucosa is:
- Ⓐ Anterior ethmoidal
  - Ⓑ Greater palatine
  - Ⓒ Nasopalatine
  - Ⓓ Posterior ethmoidal
8. The infection from the nasal cavity may spread to all of the following regions **except**:
- Ⓐ Conjunctival sac
  - Ⓑ Paranasal air sinuses
  - Ⓒ Internal ear
  - Ⓓ Anterior cranial fossa
9. The **incorrect statement** about nasal mucosa is that it is:
- Ⓐ Lined by pseudostratified ciliated columnar epithelium
  - Ⓑ Loosely adherent to the nasal septum
  - Ⓒ Lined by olfactory epithelium
  - Ⓓ Richly supplied with blood and contains cavernous spaces
10. The artery called rhinologist's artery is a septal branch of:
- Ⓐ Anterior ethmoidal artery
  - Ⓑ Superior labial artery
  - Ⓒ Greater palatine artery
  - Ⓓ Sphenopalatine artery
11. All of the following sinuses open into hiatus semilunaris **except**:
- Ⓐ Frontal
  - Ⓑ Anterior ethmoidal
  - Ⓒ Middle ethmoidal
  - Ⓓ Maxillary
12. The sinus that drains by gravity when the head is erect is:
- Ⓐ Sphenoidal

- Ⓒb) Frontal
- Ⓒc) Maxillary
- Ⓒd) None of the above

13. The **incorrect statement** about maxillary sinus is that:

- Ⓒa) It is first sinus to develop
- Ⓒb) It is the largest air sinus
- Ⓒc) It is rarely affected by the sinusitis
- Ⓒd) Its ostium lies near the roof

14. The size of the maxillary hiatus is reduced by all of the following bones **except**:

- Ⓒa) Ethmoid
- Ⓒb) Sphenoid
- Ⓒc) Lacrimal
- Ⓒd) Inferior nasal concha

15. Toothache in maxillary sinusitis occurs due to stimulation of:

- Ⓒa) Inferior alveolar nerve
- Ⓒb) Superior alveolar nerves
- Ⓒc) Greater palatine nerve
- Ⓒd) Nasopalatine nerve

16. All of the following structures open into the middle meatus of nose **except**:

- Ⓒa) Frontonasal duct
- Ⓒb) Anterior ethmoidal air sinus
- Ⓒc) Middle ethmoidal air sinus
- Ⓒd) Nasolacrimal duct

17. The postural drainage of maxillary sinus is best when:

- Ⓒa) The head is erect
- Ⓒb) Lying on the affected side
- Ⓒc) Lying on the unaffected side
- Ⓒd) Head is tilted forwards

18. Which is an independent bone:

- Ⓒa) Superior nasal concha
- Ⓒb) Middle nasal concha
- Ⓒc) Inferior nasal concha
- Ⓒd) Cribriform plate

19. All the statements about sphenoidal air sinus are correct **except**:

- Ⓒa) It drains into sphenoethmoidal recess
- Ⓒb) It lies above and behind the nasal cavity

- ☐(c) It is related laterally to the cavernous sinus
  - ☐(d) It drains into middle meatus
20. Select the **incorrect statement** about the maxillary sinus:
- ☐(a) Its floor is formed by the lateral wall of the nose
  - ☐(b) It is the largest air sinus
  - ☐(c) Its apex extends into the zygomatic process
  - ☐(d) It is most commonly infected of all the sinuses

## Answers

1. **b** , 2. **c** , 3. **b** , 4. **c** , 5. **b** , 6. **c** , 7. **c** , 8. **c** , 9. **b** , 10. **d** , 11. **c** , 12. **b** , 13. **c** , 14. **b** , 15. **b** , 16. **d** , 17. **c** , 18. **c** , 19. **d** , 20. **a**

## Chapter 18

1. Select the **incorrect statement** about the auricle of the ear:
  - ☐(a) Its skeleton is made up of yellow-elastic cartilage
  - ☐(b) Its skeleton is made up of fibrocartilage
  - ☐(c) Its lobule is devoid of cartilage
  - ☐(d) Thick hair on auricle in males represents Y-linked inheritance
2. All of the following nerves provide sensory innervation to the pinna/auricle of the external ear **except**:
  - ☐(a) Great auricular nerve
  - ☐(b) Greater occipital nerve
  - ☐(c) Auriculo-temporal nerve
  - ☐(d) Alderman's nerve
3. The lateral surface of the auricle presents all of the following features **except**:
  - ☐(a) Tragus
  - ☐(b) Cymba conchae
  - ☐(c) Eminentia triangularis
  - ☐(d) Concha
4. Select the **incorrect statement** about the external auditory meatus:
  - ☐(a) It measures about 24 mm along its posterior wall
  - ☐(b) Its outer one-third is bony and inner two-third is cartilaginous
  - ☐(c) It is narrowest where the bony and cartilaginous parts meet
  - ☐(d) Its floor is longer than its roof
5. Select the **incorrect statement** about the tympanic membrane:
  - ☐(a) Its lateral surface is concave
  - ☐(b) Its point of maximum convexity on medial surface is called

umbo

⌘(c) It provides attachment to the handle of malleus

⌘(d) It forms an obtuse angle with the floor of external auditory meatus

6. Embryologically the tympanic membrane is derived from:

⌘(a) Ectoderm

⌘(b) Mesoderm

⌘(c) Endoderm

⌘(d) All of the above

7. Which of the following quadrants of tympanic membrane is relatively safe for giving surgical incision to drain pus from middle ear?

⌘(a) Antero-superior

⌘(b) Postero-superior

⌘(c) Antero-inferior

⌘(d) Postero-inferior

8. The contents of middle ear include all **except:**

⌘(a) Tensor tympani

⌘(b) Tegmen tympani

⌘(c) Chorda tympani

⌘(d) Tympanic plexus

9. All of the following structures are of an adult size at birth **except:**

⌘(a) External ear

⌘(b) Middle ear

⌘(c) Internal ear

⌘(d) Ear ossicles

10. Medial wall of the middle ear presents all of the following features **except:**

⌘(a) Oval window

⌘(b) Round window

⌘(c) Pyramidal prominence

⌘(d) Prominence of lateral semicircular canal

11. The membranous labyrinth of internal ear consists of all **except:**

⌘(a) Cochlear canal

⌘(b) Utricle

⌘(c) Saccule

⌘(d) Cochlear duct

12. The organ of Corti is located within:

⌘(a) Semicircular ducts

- Ⓒ Utricle
- Ⓓ Saccule
- Ⓔ Cochlear duct

13. Select the **incorrect statement** about the internal ear:

- Ⓒ Sensory receptor for hearing is located in the cochlear duct
- Ⓓ Sensory receptors for static balance are located in the saccule and utricle
- Ⓔ Sensory receptors for kinetic balance are located in the semicircular canals
- Ⓕ Sensory receptor, for kinetic balance is maculae

14. All of the following structures are components of spiral organ of corti, **except:**

- Ⓒ Tunnel of Corti
- Ⓓ Hair cells
- Ⓔ Deiters cell
- Ⓕ Otolith membrane

## Answers

1. **b** , 2. **b** , 3. **c** , 4. **b** , 5. **d** , 6. **d** , 7. **d** , 8. **b** , 9. **a** , 10. **c** , 11. **a** , 12. **d** , 13. **d** , 14. **d**

## Chapter 19

1. The medial wall of the bony orbit is formed by all of the following bones **except:**

- Ⓒ Frontal process of maxilla
- Ⓓ Lacrimal bone
- Ⓔ Orbital surface of the greater wing of sphenoid
- Ⓕ Orbital plate of the ethmoid

2. Which of the following nerves lies in the orbit outside the orbital periosteum (or periorbita):

- Ⓒ Oculomotor
- Ⓓ Trochlear
- Ⓔ Abducent
- Ⓕ Zygomatic

3. Select the **incorrect statement** about the levator palpebrae superioris:

- Ⓒ It arises from the under surface of the greater wing of sphenoid near the apex of the orbit

- ⌘(b) It is supplied by oculomotor nerve and cervical sympathetic fibres
  - ⌘(c) Its paralysis causes ptosis
  - ⌘(d) It consists of both voluntary and involuntary muscle fibres
4. Select the **incorrect statement** about the ciliary ganglion:
- ⌘(a) It lies between the optic nerve and lateral rectus near the apex of the orbit
  - ⌘(b) It is functionally connected to the oculomotor nerve
  - ⌘(c) It lies between optic nerve and medial rectus near the apex of the orbit
  - ⌘(d) Topographically it is connected to the nasociliary nerve
5. All of the following statements regarding cornea are correct **except**:
- ⌘(a) It forms the anterior one-sixth of the outer coat of the eyeball
  - ⌘(b) It consists of five layers
  - ⌘(c) Its refractive power is less than that of the lens
  - ⌘(d) It is devoid of blood and lymph vessels
6. The (refractive apparatus) of eye consists of all of the following structures **except**:
- ⌘(a) Cornea
  - ⌘(b) Iris
  - ⌘(c) Lens
  - ⌘(d) Vitreous body
7. The uveal tract consists of all of the following structures **except**:
- ⌘(a) Choroid
  - ⌘(b) Ora serrata
  - ⌘(c) Ciliary body
  - ⌘(d) Iris
8. Which of the following branches of the ophthalmic artery is most important?
- ⌘(a) Lacrimal artery
  - ⌘(b) Central artery of retina
  - ⌘(c) Supraorbital artery
  - ⌘(d) Supratrochlear artery
9. All of the following muscles of eyeball are supplied by the oculomotor nerve **except**:
- ⌘(a) Superior rectus
  - ⌘(b) Superior oblique
  - ⌘(c) Inferior rectus

⌘d) Inferior oblique

10. All of the following structures are derived from Tenon's capsule **except:**

⌘a) Medial check ligament

⌘b) Lateral check ligament

⌘c) Lacrimal fascia

⌘d) Ligament of Lockwood

## Answers

1. **c** , 2. **d** , 3. **a** , 4. **c** , 5. **c** , 6. **b** , 7. **b** , 8. **b** , 9. **a** , 10. **c**

## Chapter 20

1. The contents of vertebral canal include all of the following structures **except:**

⌘a) Spinal nerve roots

⌘b) Spinal cord

⌘c) Spinal ganglia

⌘d) Spinal meninges

2. Select the **incorrect statement** about the internal vertebral venous plexus:

⌘a) It is a network of veins in the subdural space

⌘b) It receives basivertebral veins

⌘c) It drains into segmental veins

⌘d) It is continuous with the intracranial dural venous sinuses

3. All of the following statements are true regarding the spinal dura **except:**

⌘a) The spinal dura consists of single layer

⌘b) The lower end of spinal dura is pierced by the filum terminale

⌘c) The spinal dura consists of two layers

⌘d) The spinal dura ends below at the level of S2 vertebra

4. Select the **incorrect statement** about the spinal cord:

⌘a) Its average length is about 45 cm

⌘b) Its average length is about 35 cm

⌘c) In adults its lower end extends up to the lower border of L1 vertebra

⌘d) In foetus its lower end extends up to the lower border of S2 vertebra

5. The total number of spinal segments is:

- Ⓐ 30
  - Ⓑ 31
  - Ⓒ 32
  - Ⓓ 33
6. Regarding cervical enlargement of spinal cord, which of the following statement is not correct?
- Ⓐ It extends from C5 to T1 spinal segments
  - Ⓑ Its vertebral level extends from C5 to T1 vertebrae
  - Ⓒ Its vertebral level extends from C3 to T1 vertebrae
  - Ⓓ The spinal nerves arising from cervical enlargement supply upper limbs
7. Which of the following statements is **not correct** regarding the anterior spinocerebellar tract?
- Ⓐ It carries unconscious proprioceptive sensations from spinal cord to cerebellum
  - Ⓑ The cell bodies of its second order sensory neurons lie in the nucleus dorsalis (Clarke's column)
  - Ⓒ Its fibres enter the cerebellum through inferior cerebellar peduncle
  - Ⓓ Its fibres enter the cerebellum through superior cerebellar peduncle
8. Select the **incorrect statement** regarding the fasciculus gracilis and fasciculus cuneatus:
- Ⓐ They carry conscious proprioceptive sensations
  - Ⓑ They are formed by axons arising from cells in nucleus dorsalis
  - Ⓒ They are formed by axons arising from cells in the posterior root ganglia
  - Ⓓ Their fibres terminate in the nucleus gracilis and nucleus cuneatus within the medulla

## Answers

1. **c** , 2. **a** , 3. **c** , 4. **b** , 5. **b** , 6. **b** , 7. **c** , 8. **b**

## Chapter 21

1. All of the following statements about diploic veins are correct **except**:
- Ⓐ They drain blood from spongy bones skull-vault
  - Ⓑ They mostly drain into intracranial dural venous sinuses
  - Ⓒ They possess valves in their lumen

- ⌘d) There are only four pairs of recognizable diploic veins
2. Commonest site of fracture of the base of skull is
- ⌘a) Anterior cranial fossa  
⌘b) Middle cranial fossa  
⌘c) Posterior cranial fossa  
⌘d) None of the above
3. Select the **incorrect statement** about the dural venous sinuses:
- ⌘a) They are lined by endothelium  
⌘b) They have no valves  
⌘c) They communicate with extracranial veins  
⌘d) They possess thin muscle coat in their wall
4. All of the following dural venous sinuses are paired **except**:
- ⌘a) Superior petrosal  
⌘b) Inferior petrosal  
⌘c) Inferior sagittal  
⌘d) Cavernous
5. Lateral wall of cavernous contains all of the following nerves **except**:
- ⌘a) Oculomotor  
⌘b) Trochlear  
⌘c) Ophthalmic  
⌘d) Abducent
6. Which of the following dural venous sinuses is more likely to be affected in mastoiditis?
- ⌘a) Superior petrosal  
⌘b) Inferior petrosal  
⌘c) Sigmoid  
⌘d) Transverse
7. All of the following dural venous sinuses lie in between the two layers of dura mater **except**:
- ⌘a) Superior sagittal sinus  
⌘b) Inferior sagittal sinus  
⌘c) Superior petrosal sinus  
⌘d) Inferior petrosal sinus
8. Regarding pituitary gland all of the following statements are correct **except**:
- ⌘a) It lies in the sella turcica  
⌘b) It develops from two different sources  
⌘c) It is supplied by branches of middle meningeal artery

- (d) It is related on each side to the cavernous sinus  
 9. All of the following hormones are secreted by adenohypophysis **except:**  
 (a) Growth hormone  
 (b) Prolactin  
 (c) Oxytocin  
 (d) ACTH  
 10. Which of the following hormones is secreted by pars intermedia of pituitary gland?  
 (a) Oxytocin  
 (b) Melanocyte stimulating hormone (MSH)  
 (c) Antidiuretic hormone (ADH)  
 (d) Vasopressin

### Answers

1. **c** , 2. **b** , 3. **d** , 4. **c** , 5. **d** , 6. **c** , 7. **b** , 8. **c** , 9. **c** , 10. **b**

## Chapter 22

- All of the following structures pass through jugular foramen **except:**
  - Glossopharyngeal nerve
  - Vagus nerve
  - Inferior petrosal sinus
  - Hypoglossal nerve
- All of the following muscles are not supplied by glossopharyngeal nerve **except:**
  - Palatopharyngeus
  - Salpingopharyngeus
  - Stylopharyngeus
  - Superior constrictor of pharynx
- Select the **incorrect statement** about glossopharyngeal nerve:
  - It arises from medulla oblongata
  - It supplies only one muscle
  - It is involved in 'gag reflex'
  - It carries taste sensations from anterior two-third of the tongue
- Select the **incorrect statement** about vagus nerve:
  - It carries taste sensation from posteriormost part of the tongue
  - It provides secretomotor fibres to the gland of respiratory and digestive tracts

- ⌘(c) It is the largest cranial nerve
  - ⌘(d) It carries general sensations from the skin of auricle
5. The functional components of vagus nerve include all of the following **except**:
- ⌘(a) General visceral efferent (GVE)
  - ⌘(b) Special visceral efferent (SVE)
  - ⌘(c) General somatic afferent (GSA)
  - ⌘(d) Special somatic afferent (SSA)
6. All of the following branches of left vagus nerve arise in the neck **except**:
- ⌘(a) Pharyngeal branch
  - ⌘(b) Branches to carotid sinus and carotid body
  - ⌘(c) Recurrent laryngeal nerve
  - ⌘(d) Cardiac branches
7. Bilateral lesions of vagus nerve will cause all of the following signs **except**:
- ⌘(a) Nasal regurgitation of swallowed liquids
  - ⌘(b) Nasal twang of voice
  - ⌘(c) Soft palate rises in midline
  - ⌘(d) Flattening of palatal arches
8. Select the **incorrect statement** about accessory nerve:
- ⌘(a) Its both roots arise from medulla oblongata
  - ⌘(b) Its cranial root is distributed through vagus nerve
  - ⌘(c) Its spinal root supplies sternocleidomastoid and trapezius muscles
  - ⌘(d) It exits from skull through jugular foramen
9. Cranial root of the accessory nerve supplies all of the following muscles of palate through pharyngeal plexus **except**:
- ⌘(a) Tensor palati
  - ⌘(b) Palatopharyngeus
  - ⌘(c) Salpingopharyngeal muscle
  - ⌘(d) Palatoglossus
10. Select the **incorrect statement** about hypoglossal nerve:
- ⌘(a) Its rootlets arise from anterolateral sulcus of the medulla oblongata
  - ⌘(b) It supplies all the muscles of tongue *except* palatoglossus
  - ⌘(c) It lies deep to internal and external carotid arteries
  - ⌘(d) It exits from skull through anterior condylar canal

11. In lesions of right hypoglossal nerve:

- (a) Tongue deviates to right side on protrusion
- (b) Tongue deviates to left side on protrusion
- (c) Tongue fails to protrude at all
- (d) None of the above

**Answers**

1. **d** , 2. **c** , 3. **d** , 4. **c** , 5. **d** , 6. **c** , 7. **c** , 8. **a** , 9. **a** , 10. **c** , 11. **a**

# Section II Brain

## Chapter 23

1. The brainstem consists of all of the following components **except**:
  - Ⓐ Midbrain
  - Ⓑ Pons
  - Ⓒ Medulla oblongata
  - Ⓓ Cerebellum
2. Regarding cavities of brain, all of the following statements are correct **except**:
  - Ⓐ Right and left lateral ventricles are cavities within the right and left cerebral hemispheres, respectively
  - Ⓑ Third ventricle is the cavity within diencephalon
  - Ⓒ Cerebral aqueduct is the cavity within the pons
  - Ⓓ Fourth ventricle is the cavity within the hindbrain
3. Which of the following subarachnoid cisterns is largest?
  - Ⓐ Interpeduncular cistern
  - Ⓑ Cisterna ambiens
  - Ⓒ Pontine cistern
  - Ⓓ Cerebellomedullary cistern
4. The term **tela choroidea** refers to:
  - Ⓐ Ependymal element of choroid plexus
  - Ⓑ Pial element of choroid plexus
  - Ⓒ Vascular tufts of choroid plexus
  - Ⓓ None of the above
5. Regarding brain, which of the following statements is **not correct**:
  - Ⓐ Cerebrum is the largest part of the brain
  - Ⓑ Cerebellum is the second largest part of the brain
  - Ⓒ Midbrain passes through tentorial notch to join hindbrain with the forebrain
  - Ⓓ The term brainstem is usually applied to diencephalon, midbrain and pons
6. The cerebrospinal fluid (CSF) is formed mainly by:
  - Ⓐ Choroid plexuses within the lateral ventricles
  - Ⓑ Choroid plexus within the 3rd ventricle
  - Ⓒ Choroid plexus within the 4th ventricle
  - Ⓓ Ependyma of the ventricles

## Answers

1. **d** , 2. **c** , 3. **d** , 4. **b** , 5. **d** , 6. **a**

## Chapter 24

1. All of the following statements are true regarding medulla oblongata **except**:
  - Ⓐ It is the part of brainstem between pons and spinal cord
  - Ⓑ It passes through foramen magnum to the level of atlas
  - Ⓒ It is traversed by the central canal throughout its extent
  - Ⓓ Hypoglossal nerve arises from its anterior to the olive
2. Transverse section of the medulla of the level of olives shows all of the following nuclei **except**:
  - Ⓐ Hypoglossal nucleus
  - Ⓑ Nucleus of tractus solitarius
  - Ⓒ Nucleus cuneatus
  - Ⓓ Nucleus ambiguus
3. Select the **incorrect statement** about the medial lemniscus:
  - Ⓐ It consists of fibres arising from nucleus gracilis and nucleus cuneatus
  - Ⓑ It forms a part of the auditory pathway
  - Ⓒ It conducts conscious proprioceptive sensations from opposite half of the body
  - Ⓓ Its fibres terminate in the thalamus
4. Regarding pons, all of the following statements are correct **except**:
  - Ⓐ Median sulcus on its ventral surface lodges the basilar artery
  - Ⓑ The structure of basilar part is identical throughout its extent
  - Ⓒ Its dorsal part is continuous above with the tegmentum of the midbrain
  - Ⓓ It receives afferent fibres from the cerebellum through middle cerebellar peduncle
5. All of the following nuclei are found in pons at the level of facial colliculus **except**:
  - Ⓐ Abducent nucleus
  - Ⓑ Motor nucleus of trigeminal nerve
  - Ⓒ Motor nucleus of the facial nerve
  - Ⓓ Cochlear nuclei
6. The cerebral peduncle consists of all of the following parts **except**:

- ⌘(a) Crus cerebri
- ⌘(b) Substantia nigra
- ⌘(c) Tegmentum
- ⌘(d) Tectum

## Answers

1. **c** , 2. **c** , 3. **b** , 4. **d** , 5. **b** , 6. **d**

## Chapter 25

1. Select the **incorrect statement** about the cerebellum:
  - ⌘(a) It is the second largest part of the brain
  - ⌘(b) It accounts for about 10% of the total weight of the brain
  - ⌘(c) It is connected to the midbrain through middle cerebellar peduncle
  - ⌘(d) It consists of two hemispheres which are united in the midline by vermis
2. Select the **incorrect statement** about the archicerebellum:
  - ⌘(a) Phylogenetically, it is the oldest part of the cerebellum
  - ⌘(b) It consists of flocculonodular lobe and lingula
  - ⌘(c) It is primarily concerned with smooth performance of fine voluntary movements
  - ⌘(d) It is primarily concerned with maintenance of the equilibrium
3. The neocerebellum is primarily concerned with:
  - ⌘(a) Maintenance of equilibrium
  - ⌘(b) Smooth performance of fine voluntary movements
  - ⌘(c) Regulating muscle tone and posture of the trunk
  - ⌘(d) Regulating muscle tone and posture of the limbs
4. All of the following are intracerebellar nuclei **except**:
  - ⌘(a) Dentate nucleus
  - ⌘(b) Fastigial nucleus
  - ⌘(c) Globose nucleus
  - ⌘(d) Red nucleus
5. Regarding dentate nucleus of the cerebellum, all of the following statements are correct **except**:
  - ⌘(a) It is the largest intracerebellar nucleus
  - ⌘(b) Its efferent fibres form most of the superior cerebellar peduncle
  - ⌘(c) It receives afferent fibres mainly from paleocerebellum
  - ⌘(d) It receives afferent fibres mainly from neocerebellum

6. The cerebellar lesion is characterized by all of the following signs/symptoms **except**:
- Ⓐ Ataxia
  - Ⓑ Muscular hypotonia
  - Ⓒ Nystagmus
  - Ⓓ Tremors at rest

### Answers

1. **c** , 2. **c** , 3. **b** , 4. **d** , 5. **c** , 6. **d**

## Chapter 26

1. All of the following are subdivisions of diencephalon **except**:
  - Ⓐ Thalamus
  - Ⓑ Mammillary bodies
  - Ⓒ Metathalamus
  - Ⓓ Subthalamus
2. Which of the following structures is not a part of the thalamus?
  - Ⓐ Medial geniculate body
  - Ⓑ Lateral geniculate body
  - Ⓒ Pineal body
  - Ⓓ Pulvinar
3. The Y-shaped sheet of white matter that divides thalamus into its three main parts (anterior, medial, and lateral) is called:
  - Ⓐ Lamina terminalis
  - Ⓑ Stria medullaris thalami
  - Ⓒ Internal medullary lamina
  - Ⓓ Lamina cribrosa
4. Which of the following is the largest somatosensory nucleus of the thalamus?
  - Ⓐ Ventral anterior
  - Ⓑ Ventral lateral
  - Ⓒ Ventral posterior
  - Ⓓ Lateral posterior
5. Regarding pineal gland, which of the following statements is **not correct** ?
  - Ⓐ It is a neuroendocrine gland
  - Ⓑ It secretes melatonin hormone
  - Ⓒ Its influence on other endocrine glands is excitatory

- ⌘d) It is the only part of brain which does not consist of neural tissue
6. All of the following statements about hypothalamus are correct **except**:
- ⌘a) It forms the floor of the 3rd ventricle
  - ⌘b) It weighs about 4 g
  - ⌘c) It is regarded as the head ganglion of the autonomic nervous system
  - ⌘d) It is bounded anteriorly by lamina cribrosa
7. Anatomically, which of the following regions does not belong to the hypothalamus?
- ⌘a) Supraoptic region
  - ⌘b) Preoptic region
  - ⌘c) Tuberal region
  - ⌘d) Mammillary region

## Answers

1. **b** , 2. **c** , 3. **c** , 4. **c** , 5. **c** , 6. **d** , 7. **b**

## Chapter 27

1. Select the **incorrect statement** about the longitudinal cerebral fissure:
  - ⌘a) It completely separates the two cerebral hemispheres
  - ⌘b) It lodges the falx cerebri
  - ⌘c) It incompletely separates the two cerebral hemispheres
  - ⌘d) It lodges anterior cerebral vessels
2. Which of the following structures represents the submerged portion of the cerebral cortex?
  - ⌘a) Frontoparietal operculum
  - ⌘b) Insula
  - ⌘c) Hippocampus
  - ⌘d) Temporal operculum
3. The paracentral lobule is located on:
  - ⌘a) Medial surface of the cerebral hemisphere
  - ⌘b) Superolateral surface of the cerebral hemisphere
  - ⌘c) Tentorial surface of the cerebral hemisphere
  - ⌘d) Orbital surface of the cerebral hemisphere
4. The area between parieto-occipital and calcarine sulci on the medial

surfaces of the cerebral hemisphere is known as:

- ⌘(a) Paracentral lobule
- ⌘(b) Cuneus
- ⌘(c) Precuneus
- ⌘(d) Isthmus

5. Regarding Broca's area, which of the following statements is **not correct**?

- ⌘(a) It is located in the inferior frontal gyrus of the left cerebral hemisphere
- ⌘(b) It is supply of anterior cerebral artery
- ⌘(c) It is numbered as areas 45, 44
- ⌘(d) Its damage leads to motor aphasia

6. All of the following are the examples of bundles of commissural fibres **except**:

- ⌘(a) Corpus callosum
- ⌘(b) Interthalamic adhesion
- ⌘(c) Anterior commissure
- ⌘(d) Habenular commissure

7. Which of the following structures consists of both projection and commissural fibres?

- ⌘(a) Internal capsule
- ⌘(b) Pyramid
- ⌘(c) Cerebral fornix
- ⌘(d) Crus cerebri

## Answers

1. **a** , 2. **b** , 3. **a** , 4. **b** , 5. **b** , 6. **b** , 7. **c**

## Chapter 28

1. Basal nuclei include all of the following structures **except**:

- ⌘(a) Corpus striatum
- ⌘(b) Claustrum
- ⌘(c) Habenular nucleus
- ⌘(d) Amygdaloid body

2. Corpus striatum includes all of the following **except**:

- ⌘(a) Caudate nucleus
- ⌘(b) Putamen
- ⌘(c) Globus pallidus

- ❑(d) Amygdala
3. Select the **incorrect statement** about the caudate nucleus:
- ❑(a) It is comma-shaped mass of grey matter
  - ❑(b) Its head becomes continuous with thalamus
  - ❑(c) Its tail ends in relation to amygdaloid body
  - ❑(d) It represents part of neostriatum
4. Deficiency of which of the following neurotransmitters occurs in Parkinsonism:
- ❑(a) GABA
  - ❑(b) Serotonin
  - ❑(c) Acetylcholine
  - ❑(d) Dopamine
5. Part of the brain which undergoes degenerative changes in Parkinsonism is:
- ❑(a) Crus cerebri
  - ❑(b) Substantia nigra
  - ❑(c) Red nucleus
  - ❑(d) Subthalamus
6. The hippocampal formation consists of all of the following **except**:
- ❑(a) Hippocampus
  - ❑(b) Dentate gyrus
  - ❑(c) Fornix
  - ❑(d) Medial and lateral longitudinal striae
7. The main efferent tract of the amygdaloid body is:
- ❑(a) Stria medullaris thalami
  - ❑(b) Stria terminalis
  - ❑(c) Mammillothalamic tract
  - ❑(d) Fornix
8. Select the **incorrect statement** about the fornix:
- ❑(a) It constitutes the sole efferent tract of the hippocampus
  - ❑(b) It consists of both projection and commissural fibres
  - ❑(c) It is seen as an arched bundle of white fibres on the medial surface of the cerebral hemisphere
  - ❑(d) Its fibres arise mainly from mammillary body

## Answers

1. **c** , 2. **d** , 3. **b** , 4. **d** , 5. **b** , 6. **c** , 7. **b** , 8. **d**

## Chapter 29

1. All of the following arteries partake part in the formation of circle of Willis **except:**
  - ❑(a) Anterior communicating
  - ❑(b) Anterior cerebral
  - ❑(c) Middle cerebral
  - ❑(d) Posterior cerebral
2. All of the following arteries are branches of cerebral part of internal carotid artery **except:**
  - ❑(a) Anterior cerebral
  - ❑(b) Middle cerebral
  - ❑(c) Ophthalmic
  - ❑(d) Anterior inferior cerebellar
3. All of the following arteries arise from basilar artery **except:**
  - ❑(a) Posterior cerebral
  - ❑(b) Posterior inferior cerebellar
  - ❑(c) Superior cerebellar
  - ❑(d) Anterior inferior cerebellar
4. Anterior choroid artery is a branch of:
  - ❑(a) Anterior cerebral artery
  - ❑(b) Middle cerebral artery
  - ❑(c) Internal carotid artery
  - ❑(d) Posterior cerebral artery
5. Most of the superolateral surface of the cerebral hemisphere is supplied by:
  - ❑(a) Anterior cerebral artery
  - ❑(b) Middle cerebral artery
  - ❑(c) Posterior cerebral artery
  - ❑(d) None of the above
6. Great cerebral vein (of Galen) is formed by the union of:
  - ❑(a) Superficial middle cerebral veins
  - ❑(b) Internal cerebral veins
  - ❑(c) Anterior cerebral veins
  - ❑(d) Middle cerebral veins

Arterial supply of

- cerebrum, [397](#)
- face, [60](#)
- scalp, [50](#)
- teeth, [179–180](#)
- thyroid, [157](#)
- tongue, [184](#)
- tonsil, [205](#)

Artery/arteries

- alveolar
  - anterior inferior, [254](#)
  - anterior superior, [254](#)
  - posterior superior, [254](#)
- basilar, [409](#)
- caroticotympanic, [234](#) , [266](#)
- carotid
  - clinical anatomy of, [114](#)
  - common, [230–231](#)
  - external, [230–231](#)

- branches of, 231
  - internal, 243
  - branches of, 231–233
  - parts of, 231
- central, of retina, 289
- cerebellar
  - anterior inferior, 397t
  - posterior inferior, 397t
  - superior, 409
- cerebral
  - anterior, 410
  - middle, 409
- cervical
  - deep, 229
  - superficial, 77
  - transverse, 71
- Charcot, 385
- ciliary, 283
  - anterior, 289
  - posterior, 283
- communicating
  - anterior, 409
  - posterior, 410
- costocervical, 227
- ethmoidal, 283
- facial, 67t , 232
- hypophyseal, 234

- internal thoracic, 229
- labial
  - inferior, 60
  - superior, 60
- lacrimal, 283
- lingual, 231–232
- maxillary, 231
- meningeal
  - accessory, middle, 136
  - middle, 135
- of pterygoid canal, 136
- ophthalmic, 283–284
- palatine
  - ascending, 232–233
  - greater, 136
- pharyngeal, 136
  - ascending, 232–233
- scapular, dorsal, 230
- sphenopalatine, 136–137
- spinal
  - anterior, 409
  - posterior, 409
- subclavian, 225–235
  - branches of, 230
- temporal
  - deep, 234
  - superficial, 234

- thoracic, internal, [229](#)
- thyrocervical trunk, [229](#)
- thyroid
  - accessory, [157](#)
  - inferior, [156–157](#)
  - superior, [156–157](#)
- thyroidea ima, [156](#)
- vertebral, [227](#)
  - branches of, [227](#)

Asterion, [19](#)

Atlas vertebra, [45](#)

- occipitalization, [45](#)

Atlantoaxial joints, [106–107](#)

Atlanto-occipital joint, [106](#)

Atrium

- of middle meatus of nose, [244](#)

Auditory tube, [206–207](#)

Auricle, [258–262](#)

- nerve supply of, [259](#)

Atlas vertebra, [44](#)

Axis vertebra, [44](#)

## B

Bartholin's duct, [127](#)

Bell's palsy, [58](#)

Bezold's abscess, [34](#)

Black eye, [49](#)

Blepharitis, [63](#)

Blind spot, [289](#)

## Body

- amygdaloid, [391](#)
- carotid, [91–92](#)
- ciliary, [286](#)
- geniculate
  - lateral, [372–373](#)
  - medial, [372–373](#)
- pineal, [376t](#)
- trapezoid, [358](#) , [359](#)
- vitreous, [289](#) , [290](#)

## Bone/bones

- cranial
  - structure of, [260–261](#)
  - tables of, [253–254](#)
- ethmoid, [40](#)
- frontal, [36](#)
- hyoid, [27](#)
- incus, [265](#)
- interparietal, [38](#)
- lacrimal, [31](#) , [64](#) , [279](#)
- malleus, [265](#)
- mandible, [25](#)
- maxilla, [30–32](#)
- nasal, [18](#) , [246–247](#)
- occipital, [37–38](#)

- condylar part of, 38
  - squamous part of, 38
- of skull, 22
- palatine, 41
- parietal, 45t
- sphenoid, 39–40
  - greater wing of, 40
  - lesser wing of, 40
- stapes, 265
- sutural, 25–26
- temporal, 32–33
  - mastoid part of, 45t
  - petrous part of, 20
  - squamous part of, 25
  - tympanic part of, 19
- vomer, 42
- Wormian, 25–26
- zygomatic, 36

## Brain, 345t

- blood supply of, 400
- introduction to, 206–207

## Brainstem, 363

## Bregma, 35

## Buccal pad of fat, 53

## Bulb

- of internal jugular vein
  - inferior, 237

- superior, [237](#)

Bulla ethmoidalis, [250t](#)

Bundle

- medial longitudinal, [362](#)

Bursa

- nasopharyngeal, [202](#)
- subhyoid, [216](#)

## C

Calvaria, [305–306](#)

Canal/canals

- carotid, [22](#) , [33](#)
- of Schlemm, [284–285](#) , [285f](#)
- palatovaginal, [22](#) , [39](#)
- semicircular, [269](#) , [270](#)
  - ampulla of, [269](#)
  - anterior, [269–270](#)
  - lateral, [269–270](#)
  - posterior, [269](#) , [270](#)
  - superior, [269](#) , [270–272](#)
  - vomerovaginal, [23](#) , [39](#)
- vertebral, [293](#)
  - contents, [292–293](#)

Canaliculus/canaliculi

- cochlear, [33](#) , [270](#) , [310](#)
- innominatus, [21](#) , [309](#) , [322](#)
- tympanic, [21](#) , [22](#)

Canaliculus innominatus, 309

Capsule

- internal, 384
  - arterial supply of, 384–385
  - clinical anatomy of, 384
  - fibres in, 388f
  - parts of, 347

Caput succedaneum, 67t

Carotid sinus, 92

Cartilage/cartilages

- arytenoid, 218t
- corniculate, 214
- cricoid, 214
- cuneiform, 214–215
- epiglottis, 216
- of Wrisberg, 214–215
  - thyroid, 213 , 218t

Caruncle, lacrimal, 63

Case studies

- acute, parotitis, 177
- atherosclerosis
  - carotid artery, 242
- Bell's palsy, 67
- cafe coronary phenomenon, 192
- carotid artery atherosclerosis, 242
- carotid sinus syndrome, 95
- cervical spondylosis, 109

- hemiplegia, [387](#)
- hydrocephalus, [353](#)
- injury of spinal accessory nerve, [85](#)
- LMN type of facial palsy, [67](#)
- medial medullary syndrome, [364](#)
- nose bleeding, [256](#)
- papilloedema, [291](#)
- parotitis, acute, [177](#)
- pyriform fossa, [224](#)
- retinal detachment, [291](#)
- rib, cervical, [174](#)
- spinal accessory nerve, [85](#)
- scalene syndrome, [109](#)
- stone in submandibular gland, [130](#)

- stroke, 441,
- superficial wounds of neck, 77
- syndrome, thalamus, 372
- subacute combined degeneration of spinal cord, 304
- thalamic syndrome, 372
- thrombosis cavernous sinus, 67
- TMJ dislocation, 152
- tonsillitis, 211
- toxic goitre, 163
- tumour right cerebral hemisphere, 370
- wound superficial around neck, 77

Cauda equina, 294 , 296

Cave

- Meckel's, 313 , 322t , 329
- trigeminal, 322t

Cavity

- cranial, 306
- nasal, 246–247
- oral, 175–177 , 184–192 , 242

Cephalohaematoma, 49

Cerebellum, 348 , 366

- arterial supply of, 368
- clinical anatomy of, 368
- peduncles of, 368
- fissures of, 366
- functions of, 365
- lobes of, 366f

- vallecula of, [367f](#)
- vermis of, [367](#)

Cerebral cortex, [380](#)

- functional areas of, [381–382](#)

Cerebral haemorrhage, [385](#)

Cerebrospinal fluid, [352–353](#)

- absorption of, [352](#)
- clinical anatomy, [353](#)
- circulation of, [352](#)
- functions of, [352–353](#)
- production of, [352](#)

Cerebrum, [387](#)

Cervical plexus, [168](#)

Cervical spondylosis, [105](#)

Chain, sympathetic, cervical, [156](#) , [164](#)

Chalazion, [63](#)

Charcot's artery, [385](#)

Cheeks, [176](#)

Chiasma, optic, [324](#)

Choroid of eye, [324](#)

Choroid plexuses

- of fourth ventricle, [368–369](#)
- of third ventricle, [376](#)

Circulus arteriosus, [411](#)

Cistern/cisterns, [351](#)

- basal, [352](#)
- cerebellomedullary, [351–352](#)

- interpeduncular, 352
- of great cerebral vein, 352
- of lateral sulcus, 352
- pontine, 352

Cisterna ambiens, 352

Cisterna magna, 351–352

Cisternal puncture, 101 , 351–352

Clastrum, 389

Cleft, intratonsillar, 204 , 205

Clivus, 38 , 310 , 319

Cochlea, 269

- duct of, 269

Colliculus

- inferior, 361
- superior, 364t

Columella, 245

Commissures, 383

- anterior, 383
- corpus callosum, 383
- habenular, 384
- hippocampal, 384
- of cerebrum, 383
- of fornix, 384
- posterior, 385t

Conchae, nasal, 249

- inferior, 250t
- middle, 250t

- superior, 250t

Conjunctiva, 63 , 64

- bulbar, 64
- palpebral, 64

Conjunctivitis, 64

Conus elasticus, 216

Conus medullaris, 294 , 295–296

Cord, spinal. See Spinal cord

Cornea, 289

Corpus callosum, 383

- parts of, 383
- functions of, 383

Corpus striatum, 388–389

- connections of, 389

Cortex

- cerebral, 346 , 378 , 380
  - auditory, 406
  - functional areas of, 407
- visual, 382

Corti, organ of, 268 , 269

Costocervical trunk, 229–230

Cranial vault, 13 , 306

Craniometry, 24

Cranium, 26

Crista galli, 41 , 307

Crow's feet, 54

Crus cerebri, 361

CSF, [351–352](#)

Cushing's syndrome, [322](#)

## **D**

Dangerous area

- of face, [59f](#)
- of scalp, [51](#)

Deglutition, [202–203](#)

Dehiscence, Killian's, [303](#)

Dental formula, [181](#)

Diaphragma sellae, [313](#)

Diencephalon, [347](#)

Dilator pupillae, [287](#)

Diploe, [306](#)

Disc

- optic, [288–289](#)

Dislocation, of mandible, [131](#)

Diverticulum

- thyroid, [184](#)
- Zenker, [199](#)

Dorsum sellae, [308](#) , [310–311](#) , [313](#)

Duct/ducts

- nasolacrimal, [66](#)
- of cochlea, [268](#)
- parotid, [114](#) , [116](#)
- semicircular, [269](#)
- submandibular, [124](#) , [126](#) , [126f](#) , [127](#)

- thoracic, [168](#) , [172](#)
- thyroglossal, [159](#)

#### Dura mater

- cerebral, [312–315](#)
  - blood supply of, [313–315](#)
  - endosteal layer, [312](#) , [316](#)
  - meningeal layer, [312–315](#)
  - nerve supply of, [315](#)
  - venous sinuses of, [306](#) , [311](#)
- spinal, [294](#)

#### Dysphagia lusoria, [230](#)

## E

#### Ear, [265t](#)

- external, [258–262](#)
- internal, [271](#)
- middle, [267](#)
  - blood supply, [288](#)
  - boundaries of, [273–275](#)
  - communications of, [263](#)
  - contents of, [271t](#)
  - lymphatic drainage, [266](#)
  - nerve supply, [255](#)
  - walls of, [266](#) , [269](#)
- ossicles of, [265](#)

#### Ectropion, [54](#)

#### Ependyma, [351](#)

Epiphora, [54](#) , [59](#) , [67](#)

Epistaxis, [248](#) , [255](#)

Epithalamus, [347](#) , [374–375](#)

Eustachian tube, [206](#)

Evolution of head, [3–9](#) , [212](#)

Exophthalmos, pulsating, [317](#)

Eye, black, [49](#)

Eyeball, [284](#)

- tunics/layers of, [284–289](#)
- compartments, [289–290](#)

Eyelids, [62–64](#)

- blood supply of, [63](#)
- lymphatic drainage of, [51–52](#)
- structure, [62–63](#)

## **F**

Face, [52–62](#)

- aesthetic areas, [4–8](#)
- arteries of, [60](#)
- dangerous area of, [61–62](#)
- lymphatic drainage, [62](#)
- motor nerve supply, [57–59](#)
- sensory nerves of, [50t](#)
- skin of, [52–53](#)
- veins of, [61](#)

Falx cerebelli, [313](#) , [316](#)

Falx cerebri, [313](#)

## Fascia

- alar, 76
- buccopharyngeal, 76
- cervical
  - deep, 74 , 76–77
  - investing layer, 76
- colli, 76–77
- deep cervical fascia of neck, 71–76
- orbital, 275
- palpebral, 55 , 62–64
- parotid, 112 , 116
- pharyngobasilar, 197
- pretracheal, 73–74
- prevertebral, 76
- temporal, 52

## Fasciculus

- cuneatus, 304
- gracilis, 304
- medial longitudinal, 362

## Fenestra

- cochleae, 270
- vestibuli, 270

## Fibres

- arcuate, 387
- association, 383
  - short, 383
  - long, 383

- commissural, 386t
- pontocerebellar, 362
- projection, 384

Filum terminale, 294

Fissure/fissures

- choroid, 386–387
- of cerebellum, 348
- orbital
  - inferior, 283–284
  - superior, 308 , 309
- palpebral, 55
- petrotympanic, 22
- squamotympanic, 22

Fluid

- lacrimal, 64

Fold/folds

- salpingopharyngeal, 195
- sublingual, 127–128 , 183
- vestibular, 220
- vocal, 218 , 221

Fontanelle/fontanelles, 24

- anterior, 25
- posterior, 24
- mastoid, 24–25
- sphenoidal, 24–25

Foramen/foramina

- caecum, 307

- emissary sphenoidal, 308
- incisive, 207
- infraorbital, 17–18
- interventricular, 350
- jugular, 21 , 22
- lacerum, 308 , 309
- magnum, 17 , 45<sup>t</sup> , 313
- of 4th ventricle
  - lateral, 352 , 353
  - median, 351<sup>f</sup> , 352
- of Luschka, 352
- of Magendie, 352 , 353
- of Monro, 352
- of Vesalius, 21
- ovale, 309 , 329
- palatine
  - greater, 207
  - lesser, 207
- parietal, 16
- rotundum, 308
- spinosum, 308
- stylomastoid, 38 , 110 , 116

Forceps major, 383

Forceps minor, 383

Forehead, 3–4

Fornix, 385 , 392

- conjunctival, 64

## Fossa

- cranial
  - anterior, 306
  - middle, 306
  - posterior, 306
- hypophyseal, 39
- incisive, 207
- infratemporal, 132–152
- interpeduncular, 325–326
- lacrimal, 31
- of Rosenmüller, 202
- piriform, 196
- pterygopalatine, 152t
  - boundaries, 148–149
  - communications of, 149
  - contents of, 149–151
- rhomboid, 369
- sublingual, 27
- submandibular, 27
- supraclavicular
  - greater, 78
  - lesser, 78
- temporal, 18–19 , 131–132

## Fovea

- centralis, 288
- inferior, 368–369
- pterygoid, 28

- superior, 369

## Fracture/fractures

- hangman's, 108
- of hyoid bone, 43
- of mandible, 29
- of maxilla, 31
- of spine of sphenoid, 21
- of middle cranial fossa, 310

## Frankfurt's plane, 15

## Frenulum

- linguae, 183 , 186
- of lips, 175

## Frey's syndrome, 115

## Funduscopy, 288–289

## Ganglion/ganglia

- ciliary, 280 , 286 , 291t
- geniculate, 65 , 259
- otic, 152t
- impar, 170
- of hay fever, 152t
- pterygopalatine, 152t
- submandibular, 111
- sympathetic, cervical, 170–171
  - inferior, 173
  - middle, 170
  - superior, 170

## Ganglion

- ciliary, 281–282
- otic, 115 , 140–141
- pterygopalatine, 149–151
- submandibular, 129
- stellate, 170
- superior cervical sympathetic, 170

## Gigantism, 321

## Gingiva, 176–177

## Glabella, 4

## Gland/glands

- ceruminous, 260
- lacrimal, 64
  - accessory, 65
  - duct of, 65
  - nerve supply of, 65
  - orbital part of, 65
  - palpebral part of, 65
- Meibomian, 63
- of Moll, 63
- of Zeis, 63
- parathyroid, 153
  - blood supply of, 160
  - histology of, 160
  - inferior, 156
  - nerve supply of, 160

- superior, 160
- parotid, 116
  - accessory, 111
  - vascular supply of, 115
  - capsule of, 111
  - external features of, 111
  - lymphatic drainage of, 115
  - nerve supply of, 115
  - relations of, 111–112
  - structures within, 113–115
- pineal, 353
- pituitary, 320
- sublingual, 110 , 127 , 331
- submandibular, 124
  - blood supply of, 126
  - capsule, 125
  - parts, 135
  - lymphatic drainage of, 126 , 127–128
  - nerve supply of, 127
  - relations, 133–134
- tarsal, 64
- thyroid, 153–160
  - accessory, 157
  - arterial supply of, 162
  - capsules of, 154–155
  - development of, 159f
  - functions of, 153

- histology of, 159
- isthmus of, 153
- lobes of, 153 , 160
- lymphatic drainage of, 162
- nerve supply of, 162
- relations of, 162
- venous drainage of, 157

Glaucoma, 290

Globus pallidus, 389

Gnathion, 24

Goitre, 163

Gums, 176–177

Gyrus, gyri

- cingulate, 375 , 380
- frontal
  - inferior, 382
  - medial, 381
  - middle, 381
  - superior, 322t , 329
- occipitotemporal
  - lateral, 378
  - medial, 379
- orbital, 380
- parahippocampal, 380

### Joint/joints

- atlanto-axial, [106–108t](#)
- atlanto-occipital, [106](#)
- craniovertebral, [106–109](#)
- incudomalleolar, [265](#)
- incudostapedial, [265](#)
- intervertebral, cervical, [105–106](#)
- laryngeal, [196](#)
- of Luschka, [105](#)
- of ossicles of ear, [257](#)
- temporomandibular, [141–145](#)
  - blood supply of, [144](#)
  - cavity of, [142](#)
  - disc of, [142](#)
  - dislocation, [146](#)
  - ligaments of, [143f](#)
  - movements of, [144–146](#)
  - nerve supply of, [144](#)
  - relations of, [150](#)
  - stability, [144](#)

### Junction

- sclerocorneal, [278–279](#)

## K

Killian's dehiscence, [211t](#)

Krause, glands of, [65](#)

## L

Labyrinth, of ear

- bony, [269](#)
- membranous, [270](#)

Lacrimal

- apparatus, [64–67](#)
- canaliculi, [66](#)
- caruncle, [63](#)
- papilla, [66](#)
- puncta, [65](#)
- punctum, [66](#)
- sac, [64](#)

Lacus lacrimalis, [63–64](#)

Lamina/laminae

- cribrosa, [284](#)
- fusca, [286](#)
- spiral, [268](#)
- suprachoroidal, [286](#)

Langley's ganglion, [130t](#)

Laryngeal edema, [220–221](#)

Laryngeal prominence, [12](#)

Laryngocele, [220](#)

Laryngopharynx, [202](#)

Laryngoscopy, [222](#)

Larynx, [218t](#)

- blood supply of, [221](#)
- cartilages of, [221](#)
- cavity of, [219–221](#)
- inlet of, [219–221](#)
- joints, [218](#)
- ligaments, [220](#)
- lymphatic drainage of, [221](#)
- membranes, [219](#)
- mucous membrane of, [221](#)
- muscles of, [219](#)
  - actions of, [218f](#)
  - nerve supply of, [221](#)
- nerve supply of, [221](#)
- saccule of, [220](#)
- sinus of, [220](#)
- skeleton of, [215f](#)
- tuning fork of, [218](#)
- ventricle of, [220f](#)
- vestibule of, [220](#)

Le Fort's fracture, [32](#)

Lemniscus

- lateral, [359](#) , [361](#)
- medial, [361](#)
- trigeminal, [356](#) , [361](#)

Lens, [290](#)

- capsule of, [290](#)
- suspensory ligament of, [286](#)

#### Ligament/ligaments

- alar, [108t](#)
- apical, [107](#)
  - of dens, [107](#)
- check
  - lateral, [279](#)
  - medial, [279](#)
- cricotracheal, [216](#)
- cruciform, [107](#)
- flavum, [107](#)
- longitudinal
  - anterior, [107](#)
  - posterior, [107](#)
- of atlas, transverse, [108](#)
- of Berry, [73–74](#)
- of Lockwood, [279](#)
- of temporomandibular joint, [133](#) , [142](#)
- sphenomandibular, [28](#) , [143](#)
- stylohyoid, [240](#)
- stylomandibular, [240](#)
- suspensory, of eye, [279](#)

#### Ligamentum denticulatum, [292](#)

#### Ligamentum nuchae, [97](#) , [109t](#)

#### Limbic system, [390](#) , [392](#)

- functions of, [389–390](#)

- components of, 390–391

Limbus, 285

Line/lines

- mylohyoid, 27
- nuchal, 17
  - inferior, 17
  - highest, 17
  - superior, 41
- Reid's baseline, 15
- temporal, 18

Lips, 7 , 176

Little's area, 248

Locus ceruleus, 369

Lumbar puncture, 294

Lymph node/nodes

- buccal, 241
- cervical, 71–77 , 242–243t
  - anterior, 69 , 241
  - deep, 221
  - superficial, 68
- jugulo-omohyoid, 242–243t
- jugulodigastric, 242–243t
- mastoid, 71
- occipital, 70 , 91
- of head and neck, 240–243
- of Virchow, 318f
- paratracheal, 242

- parotid, 71 , 241
- postauricular/retroauricular, 71 , 241
- preauricular, 71 , 241
- prelaryngeal, 241
- pretracheal, 241
- retropharyngeal, 241 , 247
- submandibular, 71 , 247
- submental, 71 , 242

supraclavicular, 242

Lymphatic drainage

- neck
  - superficial, 71
  - deep, 240
- scalp and face, 62
- tongue, 189

## M

Macula

- lutea, 288
- of internal ear, 272

Malleus, 261

Mandible, 26–30

- age changes in, 29
- attachments on, 43f
- fracture of, 29
- ossification of, 29–30

Mastication

- muscles of, 146–148

Maxilla, 37

McEwen, triangle of, 45t

Meatus

- acoustic
  - external, 272 , 310
  - internal, 409

Meckel's (trigeminal) cave, 313 , 314f , 329

Media, retracting, of eye, 98

Medulla, 333 , 337–338

- arterial supply of, 359–360
- external features of, 356f
- internal structure of, 355–357

Membrana tectoria, 104–105 , 268 , 311

Membrane/membranes

- atlanto-occipital
  - anterior, 107
  - posterior, 107
- basilar, 304 , 310
- cricovocal, 216 , 219f
- Descemet's, 285
- of larynx, fibroelastic, 221 , 337
- periodontal, 179
- quadrate, 216
- Reissner's, 268
- tympanic, 270
- vestibular, 270

## Meninges

- of brain, [279](#)
- of spinal cord, [228](#)

## Metathalamus, [353t](#)

## Midbrain, [312](#)

- arterial supply of, [368](#)
- external features, [372](#)
- internal structure of, [360–362](#)

## Modiolus, [55–56](#) , [270](#)

## Mouth, [175–177](#)

## Mumps, [116](#)

## Muscle/muscles

- aryepiglotticus, [217f](#)
- arytenoids
  - oblique, [219](#)
  - transverse, [219](#)
- auricularis
  - anterior, [259](#)
  - posterior, [259](#)
  - superior, [259](#)
- buccinator, [27](#) , [31](#)
- compressor naris, [55](#)
- constrictor of pharynx, [134](#)
- corrugator supercilii, [48](#) , [54–55](#) , [57](#)
- cricoarytenoid
  - lateral, [217](#)
  - posterior, [223t](#)

- cricopharyngeus, 173
- cricothyroid, 156
- depressor anguli oris, 27
- depressor labii inferioris, 56
- depressor septi, 55
- digastric, 89
- dilator naris, 55
- extraocular, 276–278
  - actions of, 277–278
  - insertion of, 276–277
  - nerve supply of, 276–277
  - origin of, 277f
- genioglossus, 122–123
- geniohyoid, 121
- hyoglossus, 121
  - relations of, 122
- infrahyoid, 93–94
- lateral pterygoid, 133
- levator anguli oris, 55–57
- levator labii superioris, 58t , 67t
- levator labii superioris alaeque nasi, 54f , 55t , 56
- levator palati, 195
- levator palpebrae superioris, 276 , 278
- levator scapulae, 98
- longus capitis, 165
- longus colli, 165
- masseter, 152t

- medial pterygoid, 138
- mentalis, 56
- mylohyoid, 125
- obliquus capitis
  - inferior, 100
  - superior, 97
- occipitofrontalis, 48
- of eyeball, 64 , 255
- of facial expression, 53
- of larynx, 222
  - actions of, 223t
  - nerve supply of, 221
- of mastication, 137–139
- of pharynx, 186
  - constrictor, 198
  - longitudinal, 187t
- of tongue
  - extrinsic, 186–192
  - intrinsic, 186–192
- omohyoid, 94
- orbicularis oculi, 53–54 , 57
- orbicularis oris, 53–54
- palatoglossus, 190
- palatopharyngeus, 195
- platysma, 69 , 71
- prevertebral, 164
- pterygoid

- lateral, 123
    - relations of, 123f
  - medial, 62–64
- rectus, of eyeball
  - inferior, 279
  - lateralis, 279
  - medialis, 279
  - superior, 279
- rectus capitis
  - posterior major, 102
  - posterior minor, 100f , 102
- scalene, 173
- scalenus
  - anterior, 80
  - medius, 80
  - posterior, 79
- semispinalis capitis, 102
- semispinalis cervicis, 99
- spinalis cervicis, 99
- splenius capitis, 98
- splenius cervicis, 108t
- stapedius, 263
- sternocleidomastoid, 79–80
- sternohyoid, 94t
- sternothyroid, 93
- styloglossus, 34 , 111 , 119
- stylohyoid, 86

- stylopharyngeus, 201 , 224
- suprahyoid, 94
- temporalis, 147 , 152
- tensor palati, 208
- tensor tympani, 265
- thyroarytenoid, 218t
- thyroepiglotticus, 217
- thyrohyoid, 94
- thyropharyngeus, 214
- transverse arytenoid, 217
- trapezius, 98
- vocalis, 218
- zygomaticus major, 56
- zygomaticus minor, 56

Musculus uvulae, 208 , 209

## N

Naris, anterior, 246

Nasion, 7 , 24

Nasopharynx, 209

Neck

- anterior median region of, 86
- back of, 96–99
- deep structures in, 129
- radical dissection of, 225
- rigidity of, 96 , 99
- root of, 172–173

- side of, 85
- triangles of
  - anterior, 79
  - carotid, 80
  - digastric, 88
  - muscular, 93
  - posterior, 83
  - submental, 95
- wry neck, 80

Neocerebellum, 366 , 370

Nerve/nerves

- abducent, 327–328
- accessory, 339
  - clinical anatomy of, 335
  - cranial root of, 333
  - functional components,
  - of, 335
  - spinal root of, 337
- alveolar
  - anterior superior, 136
  - inferior, 121
  - middle superior, 121
  - posterior superior, 136
- auriculotemporal, 135
- buccal, 138
- chorda tympani, 139–140
- facial, 266 , 330–332

- frontal, 283
- glossopharyngeal, 123 , 334–335
  - branches of, 340t
  - distribution of, 335–336
  - functional components of, 364
- hypoglossal, 91 , 339–341
- infraorbital, 31 , 149–150
- infratrochlear, 281
- labial, 60
- lacrimal, 280
- laryngeal
  - external, 337
  - internal, 337
  - recurrent, 339
  - superior, 337
- lingual, 28 , 123 , 128 , 139 , 404
- mandibular, 137–139
  - branches, 137–141
- masseteric, 138
- maxillary, 149–150
  - external, 232–233
- nasociliary, 283
- oculomotor, 325–326
- olfactory, 324
- ophthalmic, 280–281 , 328–330
- optic, 348–349
- orbital, 137t

- greater, 151
  - lesser, 151
- petrosal
  - deep, 154
  - greater, 151
  - lesser, 141
- phrenic, 169–170
  - accessory, 169–170
  - distribution, 167
  - trigeminal, 328–330
  - trochlear, 326–327
- vagus, 334
  - branches of, 335
  - functional components of, 335
- vestibulo-cochlear, 332–333

Nerve point of neck, 83–84

Nerve supply of

- external ear, 259
- face, 59–60
- scalp, 50
- teeth, 179
- tongue, 190

Nervus spinosus, 137–138

Neuralgia

- trigeminal, 59

Neurohypophysis, 320

Norma (of skull)

- basalis, 15 , 20
  - foramina on, 20–21
- frontalis, 17–18
  - foramina on, 18
- lateralis, 18–20
- occipitalis, 16
- verticalis, 16

#### Nose, 249–250

- cavity of, 244
- conchae of, 244
- external, 249–250
- lateral wall, 247
  - arterial supply, 251–252
  - lymphatic drainage, 247
  - nerve supply, 251–252
- meatuses, 249–250
- septum of, 248
- vestibule, 256

#### Nostrils, 245 , 246

#### Nucleus/nuclei

- abducent, 359 , 369
- ambiguus, 357
- arcuate, 357
- basal, 347 , 392
- caudate, 388–389
- cochlear, 359
- cuneatus, 356

- dentate, [367](#)
- Edinger-Westphal, [325](#)
- emboliform, [367](#)
- facial, [381](#)
- fastigii, [367](#)
- globosus, [367](#)
- gracilis, [356](#)
- hypoglossal, [363t](#)
- lacrimatory, [363t](#)
- oculomotor, [363t](#)
- of cranial nerves, [363t](#)
- of hypothalamus, [391](#) , [392](#)
- of thalamus, [368](#)
- pontine, [368](#)
- red, [389](#)
- vestibular, [363t](#)

## O

Obelion, [16](#)

Oesophagus, [162](#)

Opisthocranium, [4](#)

Optic disc, [291](#)

Orbit

- boundaries, [275](#)
- contents of, [275–276](#)
- nerves of, [279–281](#)
- relations, [275](#)

Organ, of Corti, [268–269](#) , [269f](#)

Oropharynx, [195–196](#)

## **P**

Palate, [208](#)

- hard, [207](#)
- soft, [208–211](#)
  - blood supply of, [209](#)
  - clefts, [211](#)
  - development of, [210f](#)
  - functions of, [206](#)
  - muscles of, [208](#)
  - nerve supply of, [210](#)
  - structure of, [208](#)

Papilla, lacrimal, [66](#)

Papilloedema, [291](#) , [325](#)

Parathormone, [160](#)

Parkinsonism, [390](#)

Parotid gland, [110–116](#)

Parotid region, [110–117](#)

- bed, [110–111](#)

Passavant's ridge, [195](#)

Patey's facio-venous plane, [113–114](#)

Pathway/pathways

- optic, [290](#)

Peduncle

- cerebellar

- inferior, 357
- middle, 358
- superior, 358
- cerebral, 360–362

Periorbita, 275

Pharyngeal

- plexus of nerves, 171
- spaces, 203

Pharyngotympanic tube, 206f

Pharynx, 194f

- blood supply of, 193
- constrictors of, 335
- laryngopharynx, 202
- lymphatic drainage of, 202
- nasopharynx, 209
- nerve supply of, 201
- oropharynx, 211
- subdivisions of, 194–195
- wall of, 194

Philtrum, 7

Pia mater, 351

Pineal gland, 373–374

- functions of, 377

Pituitary gland

- connections
  - functional, 320
- blood supply, 320

- location, [319](#)

## Plane

- facio-venous, [114](#)
- Frankfurt, [15](#)

## Plexus

- neural
  - brachial, [68](#) , [74](#) , [404](#)
  - cervical, [168](#)
  - pharyngeal, [201](#)
  - tympanic, [239](#)

  - epidural, [292](#)
  - suboccipital, [109t](#)
  - vertebral, [293](#)

## Pons, [348](#)

## Pouch

- pharyngeal, [198–199](#)
- Rathke's, [194](#)

## Presbyopia, [290](#)

## Processus cochleariformis, [264f](#)

## Prominence, laryngeal, [202](#)

## Pterion, [19](#) , [20](#)

## Pulse points of

- carotid artery, [91](#)
- facial artery, [61](#)
- subclavian artery, [85](#)

- temporal artery, [5](#)

Punctum, lacrimal, [64f](#)

Pupil, [287](#)

Putamen, [389](#)

## **Q**

Quinsy, [205](#)

## **R**

Radiation

- auditory, [382](#)
- optic, [324–325](#) , [373](#)

Rathke's pouch, [194](#)

Reflex

- corneal, [286–287](#)
- cough, [211](#)
- gag, [210](#)

Refractive media, of eye, [290](#)

Region

- anterior of neck, [86](#)
- auricular, [5](#)
- buccal, [7](#)
- infratemporal, [151](#)
- mental, [4–8](#)
- nasal, [6–7](#)
- parotid, [5](#) , [116](#)
- oral, [7](#)
- submandibular, [118–130](#)
- prevertebral, [164](#)
- paravertebral, [173](#)
- respiratory, [246](#)
- parietal, [4](#)
- olfactory, [251](#)

Reid's baseline, [15](#)

Reticular formation, [363–364](#)

Retina, [287](#)

- development of, [288–289](#)
- blood supply of, [288](#)

Rhinoscopy, [251–252](#)

Rib, cervical, [230](#)

Rima glottidis, [221](#) , [223t](#)

Rima vestibuli, [220](#)

Ring, Waldeyer's, [198](#)

## **S**

Sac

- conjunctival, [64](#)
- lacrimal, [66](#)

Saccule

- of internal ear, [272](#)
- of larynx, [221](#)

Salivary glands

- large
  - parotid, [110–116](#)
  - sublingual, [127–128](#)
  - submandibular, [124–127](#)
- small, [110](#)

Schlemm canal, [284](#)

Scalp, [47](#)

- arterial supply, [50–51](#)
- dangerous layer, [49](#)
- layers, [67t](#)
- lymphatic drainage of, [51–52](#)
- nerve supply, [49](#)
- venous drainage of, [51](#)

Sclera, [284](#)

## Segment, spinal

- relationship to vertebrae, [296t](#)

## Sella turcica, [308](#)

## Septum

- blood supply, [248](#)
- clinical correlation, [248b](#)
- nasal, [250t](#)
- nerve supply, [251–252](#)
- orbital, [284](#)

## Sheath

- axillary, [75](#) , [81](#)
- carotid, [75–76](#)

## Singer's nodule, [222](#) , [223t](#)

## Sinus

- carotid, [91–92](#)
- of larynx, [222](#)
- of Morgagni, [201t](#)

## Sinus/sinuses

- paranasal, [256t](#)
  - ethmoidal, [250t](#)
  - frontal, [245](#)
  - maxillary, [250t](#)
    - carcinoma of, [255](#)
    - opening of, [255](#)
- venous, of dura mater, [306](#)
  - cavernous, [317](#)
    - clinical correlation, [317](#)

- communications of, 317
  - thrombosis of, 318
  - tributaries of, 317
- intercavernous, 317
- intracranial, 306
- occipital, 319
- petrosal
  - inferior, 319
  - superior, 319
- petrosquamous, 319
- sagittal
  - inferior, 318
  - superior, 318
- sigmoid, 317–318
- thrombosis of, 318
  - clinical anatomy, 318
- sphenoparietal, 319
- straight, 318
- transverse, 317–318

## Skeleton

- facial, 45t
- of head, and neck, 13

## Skull, 14f

- anatomical position of, 15
- base of, 25
- exterior of, 15–22
- interior of, 275

- newborn, [24–26](#)
- sex differences in, [24](#)
- vault of, [24](#) , [48](#)
- vertex of, [8t](#)
- x-ray of, [174](#)

## Space

- retropharyngeal, [210](#)

## Spinal cord, [294](#)

- blood supply of, [303](#)
- columns of
  - grey, [303](#)
  - white, [303](#)
- commissure of
  - grey, [303](#)
  - white, [298](#)
- enlargement of
  - cervical, [297](#)
  - lumbar, [297](#)
- internal structure of, [297–298](#)

## Spine

- of sphenoid, [21](#)

## Spondylosis, cervical, [105](#)

## Stapes, [265](#)

## Stenson's duct, [114–115](#)

## Striatum corpus, [388](#)

## Stye, [63](#)

## Styloid apparatus, [225](#)

Styloid process, [234](#)

Submandibular region, [118](#)

Suboccipital

- muscles, [99](#)
- regions, [99](#)
- triangle, [100–102](#)

Substantia

- ferruginea, [369](#)
- nigra, [389](#)

Subthalamus, [389](#)

Sulcus

- chiasmaticus, [308](#)
- cingulate, [379](#)
- collateral, [380](#)
- frontal
  - inferior, [379](#)
  - superior, [379](#)
- intraparietal, [379](#)
- lateral, [379](#)
  - posterior ramus of, [379](#)
  - rami of, [379](#)
- olfactory, [380](#)
- parieto-occipital, [380](#)
- tubae, [21](#)

## Suture/sutures

- coronal, 18
- frontomaxillary, 18
- frontonasal, 18
- frontozygomatic, 6 , 36 , 274
- internasal, 18
- lacrimomaxillary, 24
- lambdoid, 18–20
- metopic, 45t
- occipitomastoid, 17 , 45t

## Swallowing, 202f

## Sympathetic chain, cervical, 164 , 203

## Syndrome

- Cushing's, 322
- Frey's, 115
- Horner's, 171
- lateral medullary, 358
- temporomandibular joint, 151
- Wallenberg's, 357
- Weber's, 362

## T

## Tarsi, 63

## Tears, 65

## Teachers' nodule, 222

## Teeth, 222

- deciduous, 192t

- dentine of, 178–179
- enamel, 179
- eruption, 177
- functions of, 177
- nerve supply of, 179
- number, 181–182
- parts of, 178f
- permanent, 177
- pulp of, 183
- structure of, 179
- Temple, 4–5
- Tenon's capsule, 273

Temple, 52

Tentorium cerebelli, 313

Test

- Adson's, 174

Thalamus, 302

- clinical anatomy, 300b
- functions of, 377
- nuclei of, 374f

Thyroidectomy, 153

Tic douloureux, 59 , 330

Tongue, 184–191

- blood supply of, 193
- cancer, 190
- development of, 190–192
- external features, 200t

- lymphatic drainage of, 189f
- muscles of, 191
- nerve supply of, 191–192
- papillae of, 185
  - filiform, 185
  - fungiform, 184
  - vallate, 185

## Tonsil

- palatine, 202
  - arterial supply, 204
  - bed of, 204
  - capsule of, 205
  - lymphatic drainage of, 205
  - nerve supply of, 205
- pharyngeal, 203
- tubal, 197

Tonsillar bed, 204

Tonsillectomy, 204

Tonsillitis, 205

Torticollis, 80

Trachea, 161–162

Tracheostomy, 162

Tract/tracts

- ascending, 298
- corticospinal, 299
- descending, 299
- hypothalamohypophyseal, 375

- of spinal cord, 304t
- pyramidal, 299–300
  - lesions of, 300
- reticulospinal, 300
- of Burdach, 301–302
- spinocerebellar
  - anterior, 302
  - of Gull, 302–303
  - posterior, 302
- spinothalamic
  - anterior, 303
  - lateral, 303

Tremor, intention, 390

## Triangle

- of neck,
- anterior, 87
- carotid, 89–92
- digastric, 89
- muscular, 93
- posterior, 81–85
- scalenovertebral, 168
- of vertebral artery, 168
- submental, 88
  - posterior, 81–85
- subclavian, 174
- submandibular, 192
- suboccipital, 228

- suprameatal, [19](#)

Trigeminal neuralgia, [59](#)

Trunk

- bronchomediastinal, [172](#)
- jugular, [172](#)
- lymph, right, [172–173](#)

Tube, auditory, [194–195](#)

- clinical anatomy, [206](#)
- opening of, [206](#)

Tubercle

- carotid, [45](#)
- Chassaignac, [45](#)
- genial, [27](#)
- gracile, [355](#)
- of atlas
  - anterior, [40](#)
  - posterior, [42](#)
- Whitnall's, [63](#)

Tuberculum sellae, [39](#)

Tumour

- mixed parotid, [5](#) , [114](#)
- carotid body, [92](#)

Tuning forx of larynx, [218](#)

## U

Umbo, [261](#)

Utricle, [269](#)

Uvula, [184](#) , [208](#)

## V

Vallecula

- of cerebellum, [354–355](#)

Valve, of Hasner, [64f](#) , [66](#)

Vault of skull (skullcap), [312](#)

Vein/veins

- basal, [400](#)
- brachiocephalic, [225](#) , [235–236](#)
- cerebral, [410](#)
  - anterior, [71](#) , [410](#)
  - deep middle, [399](#)
  - external jugular, [79](#)
  - facial, [60](#)
  - great, [400](#)
  - inferior, [400t](#)
  - internal, [399–400](#)
  - retromandibular, [60](#)
  - superficial middle, [394](#)
  - superior, [397t](#)
- cervical transverse, [91](#)
- diploic, [306](#)
- emissary, [51](#)
- jugular
  - anterior, [71](#)
  - external, [70](#)

- internal, 236–238
- relations, 237
- maxillary, 150–151
- middle meningeal, 317 , 319
- ophthalmic
  - inferior, 283–284
  - superior, 291t
- pterygoid plexus of, 133
- subclavian, 235–236
- thyroid
  - fourth, 157
  - inferior, 156–157
  - middle, 157
  - of Kocher, 157
  - superior, 156–157

Venae vorticosae, 285 , 286

Venous plexus/plexuses

- pterygoid, 145

Ventricle

- of brain fourth, 350
  - boundaries of, 368–370
  - clinical anatomy, 368
  - communications of, 368
  - floor of, 368
  - roof of, 367
- lateral, 385–387
- of larynx, 221

- third, [376](#)
  - boundaries of, [375](#)
  - recesses, [375](#)

## Vermis

- of cerebellum, [369](#)

## Vertebrae

- cervical, [43–46](#)
  - first, [44](#)
  - second, [44–45](#)
  - seventh, [45–46](#)
  - transverse process, [43–46](#)
  - typical, [43](#)

## Vessels, portal, in hypophysis cerebri, [319](#)

## Vestibular folds, [220](#)

## Vestibule

- of internal ear, [267](#)
- of larynx, [221](#)
- of mouth, [175](#)

## Villi, arachnoid, [351](#)

## Vitreous body/humour, [290](#)

## Vocal cords, [219](#)

## Vocal folds, [220](#)

## Vocal nodules, [222](#)

# W

## Waldeyer's lymphatic ring, [193](#) , [198](#) , [241](#)

## Wallenburg syndrome, [357](#)

Weber's syndrome, [362](#)

Wharton's duct, [126](#)

Willis, circle of, [378](#) , [411](#) , [419–420](#)

Wing, of sphenoid

- greater, [34](#) , [40](#)
- lesser, [40](#)

Wounds

- of scalp, [51](#)

Wernicke

- speech area, [382](#)

Whitnall's tubercle, [19](#) , [63](#)

Wrisberg

- cartilage of, [224](#) , [258–259](#)

## **Z**

Zenker's diverticulum, [199](#)

Zinn, common tendinous ring, [309](#)

Zonule of Zinn, ciliary, [290](#)
